

MATH 248A. SURJECTIVITY FOR INERTIA GROUPS

Let F be complete for a non-trivial discretely-valued place, and let $F''/F'/F$ be a tower of finite extensions with F'' and F' Galois over F . We give F' and F'' their unique places extending the one on F , and so inside of $\text{Gal}(F''/F)$ and $\text{Gal}(F'/F)$ there are (by definition) inertia subgroups $I(F''/F)$ and $I(F'/F)$ that are the respective kernels

$$I(F''/F) = \ker(\text{Gal}(F''/F) \rightarrow \text{Aut}(k''/k)), \quad I(F'/F) = \ker(\text{Gal}(F'/F) \rightarrow \text{Aut}(k'/k)).$$

Thus, the natural quotient map $\text{Gal}(F''/F) \twoheadrightarrow \text{Gal}(F'/F)$ carries $I(F''/F)$ into $I(F'/F)$. We wish to show that this map of inertia groups is also surjective.

The separable closures of k in k' and k'' are the residue fields of the maximal unramified subfields F'_u and F''_u of F in F' and F'' respectively, and so the Galois property of these fields over F (why are they Galois?) implies that these respectively separable closures are Galois over k . Hence, k'/k and k''/k are normal extensions, and the fixed fields of the inertia subgroups are the respective maximal unramified subextensions (why?). Since F''_u certainly contains F'_u , we may replace F with F'_u to reduce to the case when $I(F'/F) = \text{Gal}(F'/F)$ (that is, F'/F has trivial maximal unramified subextension). In this case we need to show that $I(F''/F) = \text{Gal}(F''/F'_u)$ surjects onto $\text{Gal}(F'/F)$. Since F''_u/F is unramified and Galois yet F'/F is separable with trivial maximal unramified subextension, it follows that F''_u and F' are linearly disjoint over F . In other words, the compositum $F''_u F'$ inside of F'' is identified with $F''_u \otimes_F F'$ and so the natural injective map

$$\text{Gal}(F''_u F'/F'_u) \hookrightarrow \text{Gal}(F'/F)$$

is an isomorphism. However, the composite map

$$I(F''/F) = \text{Gal}(F''/F'_u) \twoheadrightarrow \text{Gal}(F''_u F'/F'_u) \simeq \text{Gal}(F'/F)$$

is exactly the canonical map being considered above, and so its surjectivity is now proved.

In general, if F_s/F is a separable closure and we choose an F -embedding of F' into F_s , then we use the unique extension of the place on v to a (not discretely-valued nor complete) place on F_s to define the inertia subgroup I_F in $G_F = \text{Gal}(F_s/F)$: it is the subgroup of elements that act trivially on the residue field at this place of F_s . It is clear (check!) that $I_F = \varprojlim I(F''/F)$ inside of $G_F = \varprojlim \text{Gal}(F''/F)$ with F'' ranging over the finite Galois extensions of F inside of F_s . The preceding considerations imply that if F'/F is a fixed finite Galois extension and we fix an F -embedding of F' into F_s then $I(F''/F)$ surjects onto $I(F'/F) \subseteq \text{Gal}(F'/F)$ for all F''/F' that are finite Galois over F inside of F_s . Hence, since an inverse limit of finite non-empty sets is non-empty (Zorn's Lemma), the natural map $I_F \rightarrow I(F'/F)$ must be surjective. That is, under the quotient map

$$G_F \twoheadrightarrow \text{Gal}(F'/F)$$

we have $I_F \twoheadrightarrow I(F'/F)$.

If we replace “unramified” with “tamely ramified” in everything that went before, and so replace inertia groups $I(F'/F)$ and I_F with wild inertia subgroups $P(F'/F)$ and P_F (and likewise use maximal tamely ramified subextensions to replace the role of maximal unramified subextensions) then everything goes through exactly the same way: $P(F''/F) \twoheadrightarrow P(F'/F)$ is surjective for towers $F''/F'/F$ with F'' and F' finite Galois over F , $P_F = \varprojlim P(F'/F)$ inside of G_F , and the canonical map $P_F \rightarrow P(F'/F)$ is surjective for all finite Galois extensions F'/F inside of F_s . In this way, the inertia and wild inertia groups have good analogues for F_s/F that are well-behaved with respect to passage to finite level. The same works if we replace F_s with any Galois extension of F (with possibly infinite degree), since all that was used about F_s above was that it is Galois over F .

For infinite-degree analogues of the higher ramification groups, the situation is rather more subtle and is bound up with the story of “upper numbering” that is well-explained in Serre's book *Local fields*.

In number theory, the case of most interest for the preceding considerations is that of non-archimedean local fields. For Galois towers of global fields (or possibly infinite-degree Galois extensions of global fields) we thereby get corresponding surjectivity statements for inertia and wild inertia subgroups at non-archimedean places (upon identifying the associated decomposition groups with Galois groups over a local field).
