Chapter 1. Introduction.

An important aspect of number theory is the study of so-called “Diophantine” equations. These are (usually) polynomial equations with integral coefficients. The problem is to find the integral or rational solutions. We will see that even when the original problem involves only ordinary numbers in $\mathbb{Z}$ or in $\mathbb{Q}$, one is often led to consider more general numbers, so-called algebraic numbers. Algebraic Number Theory occupies itself with the study of the rings and fields which contain algebraic numbers. The introduction of these new numbers is natural and convenient, but it also introduces new difficulties. In this introduction we follow the historical development of the subject.

Diophantus of Alexandria lived in Egypt around 300 AD. He was interested in various problems concerning rational numbers. He wrote 13 books on the subject of which only 6 remain today [15]. Those six books have been copied and translated over the centuries. Until the renaissance, they were the only available books treating these kind of number theoretical questions. The Pythagorean equation $X^2 + Y^2 = Z^2$, long known and studied before Diophantus, is a typical example of the kind of problems that are discussed in his books. Everyone knows some solutions $X,Y,Z \in \mathbb{Z}$ of this equation: one has, for instance $3^2 + 4^2 = 5^2$ and $5^2 + 12^2 = 13^2$. Diophantus gives a complete description of the set of solutions $X,Y,Z \in \mathbb{Z}$:

**Theorem 1.1.** Every solution $X,Y,Z \in \mathbb{Z}_{>0}$ with $\gcd(X,Y,Z) = 1$ of the equation

$$X^2 + Y^2 = Z^2$$

is of the form

$$X = a^2 - b^2,$$
$$Y = 2ab,$$
$$Z = a^2 + b^2,$$

(or with the roles of $X$ and $Y$ reversed) where $a,b \in \mathbb{Z}_{>0}$ satisfy $a > b > 0$ and $\gcd(a,b) = 1$.

There is no real restriction in only considering $X,Y$ and $Z$ with $\gcd(X,Y,Z) = 1$: when one divides $X,Y,Z$ by a common divisor, one still has a solution to the equation. Before proving the theorem, we prove a very important lemma.

**Lemma 1.2.** Let $a,b \in \mathbb{Z}$ be two integers with $\gcd(a,b) = 1$. If the product $ab$ is an $n$-th power for some positive integer $n$, then, up to sign, each of $a$ and $b$ is an $n$-th power.

**Proof.** This follows from the fact that every non-zero integer can be written as the product of prime numbers in a unique way: let $p$ be a prime number dividing $a$. Then $p$ also divides the product $ab$. Let $r$ indicate the number of times $ab$ is divisible by $p$. Since $\gcd(a,b) = 1$, the prime $p$ does not divide $b$. Therefore the prime number also divides $a$ exactly $r$ times.

Since $ab$ is an $n$-th power, we see that $r$ is divisible by $n$. We conclude that every prime number divides $a$ a number of times which is divisible by $n$. Therefore $a$ is, up to sign, an $n$-th power of an integer. The same is true for $b$. This proves the lemma. □

**Proof of Theorem 1.1.** It is very easy to verify that $X = a^2 - b^2, Y = 2ab$ and $Z = a^2 + b^2$ are indeed solutions to the equation $X^2 + Y^2 = Z^2$. We have to show that every solution has this form. Let therefore $X,Y,Z \in \mathbb{Z}_{>0}$ with $\gcd(X,Y,Z) = 1$ satisfy $X^2 + Y^2 = Z^2$. Since $\gcd(X,Y,Z) = 1$, at least one of $X$ and $Y$ is odd. If both were odd, we had

$$Z^2 = X^2 + Y^2 \equiv 1 + 1 = 2 \pmod{4},$$

1
which is impossible because a square is either 0 or 1 (mod 4). Therefore only one of \(X\) and \(Y\) is odd. If necessary we interchange \(X\) and \(Y\); then we may assume that \(X\) is odd. Then we have

\[
Y^2 = Z^2 - X^2 \quad \text{and} \quad \left(\frac{Y}{2}\right)^2 = \frac{Z-X}{2} \cdot \frac{Z+X}{2}.
\]

Note that both \((Z-X)/2\) and \((Z+X)/2\) are in \(\mathbb{Z}\), since both \(X\) and \(Z\) are odd. A common divisor of \((Z-X)/2\) and \((Z+X)/2\) would also divide their sum \(Z\) and their difference \(X\). Since \(X^2 + Y^2 = Z^2\), it would therefore also divide \(Y\). Since \(\gcd(X,Y,Z) = 1\), we conclude that

\[
\gcd\left(\frac{Z-X}{2}, \frac{Z+X}{2}\right) = 1.
\]

By Lemma 1.2 and the fact that both \((Z-X)/2\) and \((Z+X)/2\) are positive we see that

\[
\frac{Z-X}{2} = a^2 \quad \text{and} \quad \frac{Z+X}{2} = b^2
\]

for some \(a, b \in \mathbb{Z}_{>0}\). Since \(\gcd(X,Y,Z) = 1\) also \(\gcd(a,b) = 1\). Adding and subtracting the two equations one finds that \(Z = a^2 + b^2\) and \(X = a^2 - b^2\); this easily implies that \(Y = 2ab\). Since \(X > 0\) one has \(a > b\). This proves Theorem 1.1. \(\square\)

Pierre de Fermat (1601–1665) was a magistrate in Toulouse in France. He was one of the most famous mathematicians of the 17th century [18]. He contributed to differential calculus and probability theory. He was the only mathematician of his time to be interested in number theory. The books of Diophantus were his main source of inspiration, but Fermat went further. Fermat considered problems that were, in a sense that can be made precise (see Weil [54, Ch. II]), more difficult than the ones considered by Diophantus. He usually did not publish any proofs, but it is likely, for instance, that he had a systematic method for solving equations of the type \(X^2 - dY^2 = 1\) in integers \((d \in \mathbb{Z}_{\geq 0})\). His most famous “method” is the *method of infinite descent* that he used to solve Diophantine equations: in order to show that no integral solutions of a certain kind exist, one constructs from a hypothetical solution another solution which is, in some sense, smaller. Since integers can not be arbitrarily small, this process cannot be repeated indefinitely and one concludes that there were no solutions to begin with. Even today, Fermat’s method is one of the main tools in solving Diophantine equations. The following theorem is an example of the use of the method of infinite descent. It is one of the few proofs published by Fermat himself [18]. See also [24].

**Theorem 1.3.** *(P. de Fermat)* The only integral solutions of the equation

\[X^4 + Y^4 = Z^2\]

are the trivial ones, i.e., the ones with \(XYZ = 0\).

**Proof.** Suppose \(X, Y, Z\) is a non-trivial solution of this equation and let’s suppose this solution is *minimal* in the sense that \(|Z| > 0\) is minimal. This is easily seen to imply that \(\gcd(X, Y, Z) = 1\). We may and do assume that \(X, Y, Z > 0\). By considering the equation modulo 4, one sees that precisely one of \(X\) and \(Y\) is odd. Let’s say that \(X\) is odd. By Theorem 1.1 there are integers \(a > b > 0\) with \(\gcd(a, b) = 1\) and

\[
X^2 = a^2 - b^2, \\
Y^2 = 2ab, \\
Z = a^2 + b^2.
\]
Consider the first equation \( X^2 + b^2 = a^2 \). Since \( \gcd(a, b, X) = 1 \), we can apply Theorem 1.1 once more and we obtain
\[
X = c^2 - d^2,  \\
b = 2cd,  \\
a = c^2 + d^2,
\]
for certain integers \( c > d > 0 \) which satisfy \( \gcd(c, d) = 1 \). Substituting these expressions for \( a \) and \( b \) in the equation \( Y^2 = 2ab \) above, we find
\[
Y^2 = 2ab = 2(2cd)(c^2 + d^2)  \\
\text{and so } \left(\frac{Y}{2}\right)^2 = c \cdot d \cdot (c^2 + d^2).
\]
The numbers \( c, d \) and \( c^2 + d^2 \) have no common divisors and their product is a square. By lemma 1.2 there exist integers \( U, V, W \) with
\[
c = U^2,  \\
d = V^2,  \\
c^2 + d^2 = W^2.
\]
It is easy to see that \( \gcd(U, V, W) = 1 \) and that
\[
U^4 + V^4 = W^2.
\]
We have obtained a new solution of the equation! It is easily checked that \( W \neq 0 \) and that \( |W| \leq W^2 = c^2 + d^2 = a < a^2 < |Z| \). This contradicts the minimality of \( |Z| \). We conclude that there are no non-trivial solutions of the equation, as required.

Fermat made many statements without giving a proof for them. In many cases one is tempted to believe that he actually possessed proofs, but sometimes this is not so clear. Fermat claimed, for instance, that it is possible to write a prime number \( p \neq 2 \) as the sum of two squares if and only if it is congruent to 1 (mod 4). This fact was only proved some 100 years later by Euler (in 1754). Fermat also stated that every integer is the sum of four squares. This “non inelegens theorema” (according to Euler), was not proved until 1770 by Lagrange. It is, however, conceivable that Fermat could prove this.

But Fermat also thought that for \( k = 0, 1, 2, \ldots \) the numbers
\[
F_k = 2^{2^k} + 1
\]
(nowadays called Fermat numbers) are always prime. It is easily checked that \( F_0, F_1, \ldots, F_4 \) are prime indeed, but Euler showed in 1732 that \( F_5 = 4294967297 \) is divisible by 641. Nowadays one knows for many values \( k \geq 5 \) that \( F_k \) is not prime, and in fact, there is no single value \( k \geq 5 \) for which \( F_k \) is known to be prime. So, Fermat was not always right ...

The most famous claim by Fermat is the statement that for \( n \geq 3 \) the equation
\[
X^n + Y^n = Z^n
\]
does not admit any non-trivial solutions, i.e., it does not have solutions \( X, Y, Z \in \mathbb{Z} \) with \( XYZ \neq 0 \). Fermat wrote in the his copy of Diophantus’s book on number theory that he had a wonderful proof of this fact, but that, unfortunately, the margin was too narrow to contain it:
Cubum autem in duos cubos, aut quadratoquadrum in duos quadratoquadratos et generaliter nullam in infinitum ultra quadratum potestatem in duos eiusdem nominis fas est dividere cuius rei demonstrationem mirabilem sane detexi. Hanc marginis exquisitas non caperet.

Sooner or later all of Fermat’s statements were proved or disproved, except—for a very long time—this last one. It was called “Fermat’s Last Theorem”.

The following is an easy consequence of Theorem 1.3.

**Theorem 1.4.** Fermat’s Last theorem is true if and only if for every prime number \( p \neq 2 \), the equation

\[
X^p + Y^p = Z^p
\]

only admits trivial solutions, i.e., only solutions \( X, Y, Z \in \mathbb{Z} \) with \( XYZ = 0 \).

**Proof.** If Fermat’s Last Theorem is true, it is in particular true for prime exponents \( p > 2 \). To prove the converse, let \( n \geq 3 \) and let \( x, y, z \in \mathbb{Z} \) be a solution to the equation \( X^n + Y^n = Z^n \). We distinguish two cases: suppose first that \( n \) is divisible by an odd prime number \( p \). Then we have

\[
\left(\frac{x^n}{p}\right)^p + \left(\frac{y^n}{p}\right)^p = \left(\frac{z^n}{p}\right)^p,
\]

which is a solution to the equation \( X^p + Y^p = Z^p \). So, it should be trivial: \( (xyz)^n/p = 0 \). This implies that \( xyz = 0 \). If \( n \) is not divisible by any odd prime number, then it is a power of 2 and hence at least 4. We have

\[
\left(\frac{x^n}{4}\right)^4 + \left(\frac{y^n}{4}\right)^4 = \left(\frac{z^n}{4}\right)^2,
\]

which is a solution to the equation \( X^4 + Y^4 = Z^2 \). By Theorem 1.3 it should be trivial. This implies that \( xyz = 0 \) as required. \( \square \)

For a long time, the most important result concerning Fermat’s Last theorem was proved in 1847 by the German mathematician E.E. Kummer (1820–1889). Like Fermat, Kummer employed the method of infinite descent, but he was led to generalize the method to rings of integers other than \( \mathbb{Z} \). More precisely, let \( p \neq 2 \) be a prime and let \( \zeta_p \) denote a primitive \( p \)-th root of unity. Kummer worked with the ring \( \mathbb{Z}[\zeta_p] \) rather than with the ordinary ring of integers \( \mathbb{Z} \). Since \( X^p + 1 = \prod_{i=0}^{p-1} (X + \zeta_p^i) \), he could write

\[
X^p + Y^p = \prod_{i=0}^{p-1} (X + \zeta_p^i Y) = Z^p .
\]

He proceeded to show that the factors in the product have almost no factors in common and then he wanted to apply Lemma 1.2 to conclude that up to a unity every factor \( X + \zeta_p^i Y \) is a \( p \)-th power. He then could conclude the proof in a way which is not relevant here [30]. However, as Kummer discovered, the property of unique factorization does not, in general, hold for the rings \( \mathbb{Z}[\zeta_p] \) and in such a case one cannot apply Lemma 1.2. The first time it fails is for \( p = 23 \); it fails, in fact, for every prime \( p \geq 23 \). Using his theory of ideal numbers [17], out of which our modern concept of “ideal” was to grow, Kummer circumvented the difficulties caused by the failure of unique factorization. For the sake of completeness we quote his famous result.
Theorem 1.5. Let \( p \neq 2 \) be a prime. If \( p \) does not divide the numerators of the Bernoulli numbers \( B_2, B_4, \ldots, B_{p-3} \), then the equation

\[
X^p + Y^p = Z^p
\]

admits only solutions \( X, Y, Z \in \mathbb{Z} \) with \( XY Z = 0 \).

Here the Bernoulli numbers are rational numbers defined by the Taylor series expansion

\[
\frac{X}{e^X - 1} = \sum_{k=0}^{\infty} \frac{B_k}{k!} X^k.
\]

Since \( X/(e^X - 1) + X/2 = \frac{X}{2} \coth(\frac{X}{2}) \) is an even function, we see that \( B_1 = -1/2 \) and that the Bernoulli numbers \( B_k \) are zero for odd \( k \geq 3 \). The first few are:

\[
B_2 = \frac{1}{6}, \quad B_4 = -\frac{1}{30}, \quad B_6 = \frac{1}{42}, \quad B_8 = -\frac{1}{30},
\]

\[
B_{10} = \frac{5}{66}, \quad B_{12} = -\frac{691}{2730}, \quad B_{14} = \frac{7}{6}, \quad B_{16} = -\frac{3617}{510}, \quad \ldots
\]

They occur in the values of the Riemann \( \zeta \)-function at even integers:

\[
\zeta(k) = \sum_{n=1}^{\infty} \frac{1}{n^k} = -\frac{(2\pi)^k}{2 \cdot k!} B_k.
\]

See [1] for a table of Bernoulli numbers. From the values of the first few Bernoulli numbers one deduces that Kummer’s theorem does apply for \( p = 691 \) or 3617. The theorem applies for all primes \( p < 100 \) except 37, 59 and 67.

Subsequent numerical calculations concerning Fermat’s Last Theorem have always been based on Kummer’s Theorem or refinements thereof. In 1992, it had in this way been checked by means of computers that Fermat’s Last Theorem is correct for all exponents \( n < 4000000 \) (see [8]).

In the summer of 1993, the British mathematician Andrew Wiles finally announced a proof of Fermat’s Last Theorem. His proof employs a variety of sophisticated techniques and builds on the work of many mathematicians. One of the principal ingredients is the abstract algebraic geometry developed by A. Grothendieck [22] in the 1960’s, another is the theory of automorphic forms and representation theory developed by R. Langlands [20]. A third technique is the new method of “Euler systems” introduced by the Russian mathematician V.B. Kolyvagin [29] in the late 1980’s. Wiles actually proves part of the so-called Shimura-Taniyama-Weil conjecture concerning the arithmetic of elliptic curves over \( \mathbb{Q} \). It had already been shown in 1986 by the Americans K. Ribet and B. Mazur that this conjecture implies Fermat’s Last Theorem. Their methods depend on the arithmetic theory of modular curves [45] and like Wiles’s work, on Grothendieck’s algebraic geometry. A crucial ingredient is an important result by B. Mazur [40], proved in 1976. One can interpret this result as the simultaneous solution of infinitely many Diophantine equations. Mazur’s method is Fermat’s method of infinite descent, couched in the language of flat cohomology.

We complete this introduction by illustrating what kinds of problems one encounters when one introduces other rings of integers when trying to solve Diophantine equations. We will do calculations in the ring \( \mathbb{Z}[i] \) of Gaussian integers.
Proposition 1.6. The ring $\mathbb{Z}[i]$ of Gaussian integers is a unique factorization domain. The unit group $\mathbb{Z}[i]^*$ of this ring is \{1, -1, i, -i\}.

Proof. By Exercise 1.C, the ring $\mathbb{Z}[i]$ is a Euclidean ring with respect to the norm map $N: \mathbb{Z}[i] \rightarrow \mathbb{Z}$ given by $N(a + bi) = a^2 + b^2$ (for $a, b \in \mathbb{Z}$). It is therefore a principal ideal ring and hence a unique factorization domain. This proves the first statement. The second statement is just Exercise 1.B. \qed

Theorem 1.7. The only solution $X, Y \in \mathbb{Z}$ of the equation

$$X^3 = Y^2 + 1$$

is given by $X = 1$ and $Y = 0$.

Proof. Let $X, Y \in \mathbb{Z}$ be a solution. If $X$ were even, we would have $Y^2 = X^3 - 1 \equiv -1 \pmod{4}$ and that is impossible by Exercise 1.A. Therefore $X$ is odd. We write, in the ring $\mathbb{Z}[i]$

$$X^3 = (Y + i)(Y - i).$$

A common divisor of $Y + i$ and $Y - i$ divides their difference $2i$ and hence 2. This common divisor also divides the odd number $X^3$ and hence the gcd of $X^3$ and 2, which is 1. We conclude that $Y + i$ and $Y - i$ have no common divisor. By Prop. 1.6, the ring $\mathbb{Z}[i]$ is a unique factorization domain and we can apply a generalization of Lemma 1.2: since the product of $Y + i$ and $Y - i$ is a cube, each is, up to a unit, itself a cube. Since the unit group of $\mathbb{Z}[i]$ has order 4 by Prop. 1.6, every unit is a cube and we see that, in fact,

$$Y + i = (a + bi)^3$$

for some $a + b \in \mathbb{Z}$. We do not need the analogous equation for $Y - i$. Equating real and imaginary parts, we find that

$$Y = a^3 - 3ab^2 \quad \text{and} \quad 1 = 3a^2b - b^3.$$ 

The second relation says that $b(3a^2 - b^2) = 1$. Therefore $b = 1$ and $3a^2 = -1$ or $b = -1$ and $3a^2 - 1 = -1$. Only the second possibility gives rise to a solution of the equation $X^3 = Y^2 + 1$ viz., $Y = 0$ and $X = 1$ as required. \qed

Next we consider an altogether similar equation:

$$X^3 = Y^2 + 19.$$ 

We solve it in a similar way: if $X$ were even, we would have $Y^2 = X^3 - 19 \equiv 0 - 19 \equiv 5 \pmod{8}$, but this is impossible, since odd squares are congruent to 1 (mod 8). If $X$ were divisible by 19, also $Y$ would be divisible by 19. This implies that $19 = X^3 - Y^2$ is divisible by 19, but that is absurd. We conclude that $X$ is divisible by neither 19 or 2.

In the ring $\mathbb{Z}[\sqrt{-19}]$ we write

$$X^3 = (Y + \sqrt{-19})(Y - \sqrt{-19}).$$

A common divisor $\delta \in \mathbb{Z}[\sqrt{-19}]$ of $Y + \sqrt{-19}$ and $Y - \sqrt{-19}$ divides the difference $2\sqrt{-19}$ and hence 2 \cdot 19. Since $Y^2 + 19 = X^3$, it also divides $X^3$. Therefore $\delta$ divides the gcd of $X^3$ and 2 \cdot 19 which is equal to 1. We conclude that the factors $Y + \sqrt{-19}$ and $Y - \sqrt{-19}$ have no common divisor.

By Exercise 1.D, the only units of the ring $\mathbb{Z}[\sqrt{-19}]$ are 1 and $-1$. By a generalization of Lemma 1.2, we conclude that, since the product $(Y + \sqrt{-19})(Y - \sqrt{-19})$ is a cube, each of the
factors $Y + \sqrt{-19}$ and $Y - \sqrt{-19}$ is, up to a sign, itself a cube. Since $-1$ is itself a cube, this means that
\[ Y + \sqrt{-19} = (a + b\sqrt{-19})^3 \]
for some $a, b \in \mathbb{Z}$, taking real and imaginary parts we find
\[ Y = a^3 - 3 \cdot 19ab^2 \quad \text{and} \quad 1 = 3a^2b - 19b^3. \]
It is easy to see that already the second equation $b(3a^2 - 19b^2) = 1$ has no solutions $a, b \in \mathbb{Z}$. As in the previous example one would now like to conclude that the original equation $X^3 = Y^2 + 19$ has no solutions either, but this is not true at all, as is shown by the following equality:
\[ 7^3 = 18^2 + 19. \]
What went wrong? The problem is that one can only apply Lemma 1.2, or a simple generalization thereof, if the ring under consideration admits unique factorization. The ring $\mathbb{Z}[\sqrt{-19}]$ does not have this property:
\[ 35 = 5 \cdot 7 = (4 + \sqrt{-19})(4 - \sqrt{-19}) \]
are two distinct factorizations of the number 35 in the ring $\mathbb{Z}[\sqrt{-19}]$. We check that the factors are irreducible elements. By Exercise 1.D the norm map
\[ N: \mathbb{Z}[\sqrt{-19}] \rightarrow \mathbb{Z} \]
given by $N(a + b\sqrt{-19}) = a^2 + 19b^2$, is multiplicative. We have $N(5) = 25$, $N(7) = 49$ and $N(4 \pm \sqrt{-19}) = 19 = 35$. If any of these numbers were reducible in the ring $\mathbb{Z}[\sqrt{-19}]$, there would be elements in this ring of norm 5 or 7. Since the equations $a^2 + 19b^2 = 5$ and $a^2 + 19b^2 = 7$ have no solutions $a, b \in \mathbb{Z}$, there are no such elements. We conclude that the number 35 admits two genuinely distinct factorizations into irreducible elements. Therefore the ring $\mathbb{Z}[\sqrt{-19}]$ is not a unique factorization domain. See Exercise 10.J for a proper solution of this Diophantine equation.

In this course we study number fields and their rings of integers. The rings $\mathbb{Z}[i]$ and $\mathbb{Z}[\sqrt{-p}]$ are examples of such rings. In general, the property of unique factorization does not hold for these rings, but it can be replaced by a unique factorization property of ideals. This will be shown in Chapter 5. There we also introduce the class group, which measures the failing of the unique factorization property: it is trivial precisely when the ring of integers is a unique factorization domain. In Chapter 10 we show that the class group is finite and in Chapter 11 we prove Dirichlet’s Unit Theorem, giving a description of the structure of the unit group of a ring of integers. The main ingredient in the proofs is Minkowski’s “Geometry of Numbers”. In Chapter 12 we show how one can apply the theory in explicitly given cases. We discuss three elaborate examples. Finally in Chapter 13, we compute the residue of the Dedekind $\zeta$-function and obtain the “class number formula”.

The present theory is discussed in a great many books. We mention the book by Ono [43], Stewart and Tall [50] and Samuel [47]. The books by Lang [32], Janusz [28] and Borević and Shafarevič [5], cover more or less the same material, but also a great deal more.

**Exercises**

1. Let $x \in \mathbb{Z}$. Show:
(i) $a^2 \equiv 0$ or $1$ (mod 4);
(ii) $a^2 \equiv 0, 1$ or $4$ (mod 8).

(1.B) Let $\mathbb{Z}[i] = \{a + bi | a, b \in \mathbb{Z}\}$ be the ring of Gaussian integers. Let $N: \mathbb{Z}[i] \to \mathbb{Z}$ be the norm map defined by $N(a + bi) = a^2 + b^2$. Prove:
(i) $N(\alpha \beta) = N(\alpha)N(\beta)$ for $\alpha, \beta \in \mathbb{Z}[i]$.
(ii) If $\alpha, \beta \in \mathbb{Z}[i]$ and $\alpha$ divides $\beta$ then $\alpha$ divides $N(\beta)$.
(iii) $\alpha$ is a unit of $\mathbb{Z}[i]$ if and only if $N(\alpha) = 1$.
(iv) The group $\mathbb{Z}[i]^*$ is equal to $\{\pm 1, \pm i\}$. 

(1.C) Show that the ring $\mathbb{Z}[i]$ is Euclidean with respect to the norm $N(a + bi) = a^2 + b^2$.

(1.D) Let $\mathbb{Z}[\sqrt{-19}] = \mathbb{Z}[X]/(X^2 + 19)$. Let $N: \mathbb{Z}[\sqrt{-19}] \to \mathbb{Z}$ be the norm map defined by $N(a + b\sqrt{-19}) = a^2 + 19b^2$. Show:
(i) $N(\alpha \beta) = N(\alpha)N(\beta)$ for $\alpha, \beta \in \mathbb{Z}[\sqrt{-19}]$.
(ii) If $\alpha, \beta \in \mathbb{Z}[\sqrt{-19}]$ and $\alpha$ divides $\beta$ then $N(\alpha)$ divides $N(\beta)$.
(iii) $\alpha$ is a unit of $\mathbb{Z}[\sqrt{-19}]$ if and only if $N(\alpha) = 1$.
(iv) The group $\mathbb{Z}[\sqrt{-19}]^*$ is equal to $\{\pm 1\}$.

(1.E) Show that the ring $\mathbb{Z}[\sqrt{-2}]$ is Euclidean with respect to the norm map $N(a + b\sqrt{-2}) = a^2 + 2b^2$ $(a, b \in \mathbb{Z})$.

(1.F) Show that the only solutions $X, Y \in \mathbb{Z}$ of the equation $X^2 + 2 = Y^3$ are $X = \pm 5$ and $Y = 3$. (Hint: use Exercise 1.E)

(1.G) Show that the only solutions of the equation $Y^2 + 4 = X^3$ are $X = 5, Y = \pm 11$ and $X = 2, Y = \pm 2$.
(Hint: distinguish the cases $Y$ is odd and $Y$ is even. In the second case one should divide by $2i + 2$.)

(1.H) Show that $6 = 2 \cdot 3$ and $6 = (1 + \sqrt{-5})(1 - \sqrt{-5})$ are two factorizations of 6 into irreducible elements in the ring $\mathbb{Z}[\sqrt{-5}]$. Conclude that the ring $\mathbb{Z}[\sqrt{-5}]$ does not admit unique factorization.

(1.I) Show that the ring $\mathbb{Z}[(1 + \sqrt{-19})/2]$ is not Euclidean. We will see in Chapter 10 that it is a unique factorization domain.

(1.J) The goal of this exercise is to show that a prime number $p \neq 2$ can be written as the sum of two squares if and only if $p \equiv 1$ (mod 4). Let $p \neq 2$ be a prime number.
(i) Show that if $p = a^2 + b^2$ for certain integers $a$ and $b$, then $p \equiv 1$ (mod 4).

Let now $p \equiv 1$ (mod 4). Prove:
(ii) There exists $z \in \mathbb{Z}$ with $|z| < p/2$ and $z^2 + 1 \equiv 0$ (mod $p$).
(iii) The ideal $(z - i, p) \subset \mathbb{Z}[i]$ is generated by one element $\pi$.
(iv) $N(\pi) = p$. Conclude that $p = a^2 + b^2$ for certain $a, b \in \mathbb{Z}$.

(1.K) Show that a prime number $p \neq 3$ can be written as $p = a^2 + ab + b^2$ for certain $a, b \in \mathbb{Z}$ if and only if $p \equiv 1$ (mod 3).

(1.L) (Fermat Numbers).
(i) Let $n \in \mathbb{Z}_{>0}$. Show: if $2^n + 1$ is prime, then $n$ is a power of 2.

For $k \geq 0$ let $F_k = 2^{2^k} + 1$.
(ii) Show that every divisor of $F_k$ is congruent to 1 (mod $2^{k+1}$).
(iii) Let $k \geq 2$. Show that the square of $2^{2^{k-2}} + 2^{-2^{k-2}}$ in $\mathbb{Z}/F_k\mathbb{Z}$ is equal to 2.
(iv) Let $k \geq 2$. Show that every divisor of $F_k$ is congruent to 1 (mod $2^{k+2}$).
Chapter 2. Number fields.

In this chapter we discuss number fields. We define the real $n$-dimensional vector space $F \otimes \mathbb{R}$ associated to a number field $F$ of degree $n$. We define a homomorphism $\Phi: F \to F \otimes \mathbb{R}$ which should be seen as a generalization of the natural map $\mathbb{Q} \to \mathbb{R}$. At the end of the chapter we discuss cyclotomic fields.

**Definition 2.1.** A number field $F$ is a finite field extension of $\mathbb{Q}$. The dimension of $F$ as a $\mathbb{Q}$-vector space is called the degree of $F$. It is denoted by $[F : \mathbb{Q}]$.

Examples of number fields are $\mathbb{Q}$, $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{3}, \sqrt{7})$ and $\mathbb{Q}(\sqrt{2}, \sqrt{1+\sqrt{2}})$, of degrees 1, 2, 4, 6 and 4 respectively. The following theorem says that every number field can be generated by a single element. This element is by no means unique, though.

**Theorem 2.2.** (Theorem of the primitive element.) Let $F$ be a finite extension of $\mathbb{Q}$. Then there exists $\alpha \in F$ such that $F = \mathbb{Q}(\alpha)$.

**Proof.** It suffices to consider the case where $F = \mathbb{Q}(\alpha, \beta)$. The general case follows by induction. We must show that there is an element $\theta \in F$ such that $\mathbb{Q}(\alpha, \beta) = \mathbb{Q}(\theta)$. By choosing an embedding $F \hookrightarrow \mathbb{C}$ we may view $F$ as a subfield of $\mathbb{C}$.

We will take for $\theta$ a suitable linear combination of $\alpha$ and $\beta$. Let $f(T) = f_{\min}(T)$ the minimum polynomial of $\alpha$ over $\mathbb{Q}$. Let $n = \deg(f)$ and let $\alpha = \alpha_1, \alpha_2, \ldots, \alpha_n$ be the zeroes of $f$ in $\mathbb{C}$. The $\alpha_i$ are all distinct. (Prove yourself that this is true!) Similarly we let $g(T) = f_{\min}(T)$ be the minimum polynomial of $\beta$ over $\mathbb{Q}$. Let $m = \deg(g)$ and let $\beta = \beta_1, \beta_2, \ldots, \beta_m$ be the zeroes of $g$ in $\mathbb{C}$. Since $\mathbb{Q}$ is an infinite field, we can find $\lambda \in \mathbb{Q}^*$ such that

$$
\lambda \neq \frac{\alpha_i - \alpha}{\beta - \beta_j} \quad \text{for } 1 \leq i \leq n \text{ and } 2 \leq j \leq m,
$$

or equivalently,

$$
\alpha + \lambda\beta \neq \alpha_i + \lambda\beta_j \quad \text{for } 1 \leq i \leq n \text{ and } 2 \leq j \leq m.
$$

Put

$$
\theta = \alpha + \lambda\beta.
$$

The polynomials $h(T) = f(\theta - \lambda T)$ and $g(T)$ are both in $\mathbb{Q}(\theta)[T]$ and they both have $\beta$ as a zero. The remaining zeroes of $g(T)$ in $\mathbb{C}$ are $\beta_2, \ldots, \beta_m$ and those of $h(T)$ are $(\theta - \alpha_i)/\lambda$ for $2 \leq i \leq n$. By our choice of $\lambda$, we have that $\beta_j \neq (\theta - \alpha_i)/\lambda$ for all $1 \leq i \leq n$ and $2 \leq j \leq m$. Therefore the gcd of $h(T)$ and $g(T)$ in the ring $\mathbb{Q}(\theta)[T]$ is $T - \beta$. In particular, $T - \beta$ lies in $\mathbb{Q}(\theta)[T]$. This implies that $\beta \in \mathbb{Q}(\theta)$ and hence that $\alpha = \theta - \lambda\beta \in \mathbb{Q}(\theta)$. It follows that $\mathbb{Q}(\alpha, \beta) = \mathbb{Q}(\theta)$, as required.

**Corollary 2.3.** Let $F$ be a finite extension of degree $n$ of $\mathbb{Q}$. Then there are exactly $n$ distinct field homomorphisms $\varphi: F \to \mathbb{C}$.

**Proof.** By Theorem 2.2 we can write $F = \mathbb{Q}(\alpha)$ for some $\alpha$. Let $f$ be the minimum polynomial of $\alpha$ over $\mathbb{Q}$. A homomorphism $\varphi$ from $F$ to $\mathbb{C}$ induces the identity on $\mathbb{Q}$ (see Exercise 2.D). Therefore it is determined by the image $\varphi(\alpha)$ of $\alpha$. We have $0 = \varphi(f(\alpha)) = f(\varphi(\alpha))$. In other words, $\varphi(\alpha)$ is a zero of $f(T)$. Conversely, every zero $\beta \in \mathbb{C}$ of $f(T)$ gives rise to a homomorphism $\varphi: F \to \mathbb{C}$ given by $\varphi(\alpha) = \beta$. As the zeroes of $f$ in $\mathbb{C}$ are all distinct, there are as many homomorphism $F \to \mathbb{C}$ as the degree $n$ of $f$, as required. \qed
Proposition 2.4. Let $F$ be a number field of degree $n$ over $\mathbb{Q}$. Let $\omega_1, \ldots, \omega_n \in F$. Then

$$\omega_1, \ldots, \omega_n$$

form a basis for $F$ as a $\mathbb{Q}$-vector space if and only if $\det(\varphi(\omega_i))_{\varphi, i} \neq 0$. Here $i$ runs from 1 to $n$ and $\varphi$ runs over all homomorphisms $\varphi : F \to \mathbb{C}$.

Proof. First of all, note that by Cor. 2.3, the matrix $(\varphi(\omega_i))_{\varphi, i}$ is a square matrix! Suppose that there exists a relation $\sum_i \lambda_i \omega_i = 0$ with $\lambda_i \in \mathbb{Q}$ not all zero. Since $\varphi(\lambda) = \lambda$ for every $\lambda \in \mathbb{Q}$, we see that $\sum_i \lambda_i \varphi(\omega_i) = 0$ for every $\varphi : F \to \mathbb{C}$. This implies that $\det(\varphi(\omega_i))_{\varphi, i} = 0$.

To prove the converse, we write $F = \mathbb{Q}(\alpha)$ for some $\alpha$. Consider the $\mathbb{Q}$-basis $1, \alpha, \alpha^2, \ldots, \alpha^{n-1}$. For this basis the the matrix

$$(\varphi(\omega_i))_{\varphi, i} = (\varphi(\alpha)^{i-1})_{\varphi, i}$$

is a Vandermonde matrix (see Exercise 2.E) with determinant equal to a product of terms of the form $(\varphi_1(\alpha) - \varphi_2(\alpha))$ with $\varphi_1 \neq \varphi_2$. Since the zeroes $\varphi(\alpha) \in \mathbb{C}$ of the minimum polynomial of $\alpha$ are all distinct, this determinant is not zero.

So, for the basis $1, \alpha, \alpha^2, \ldots, \alpha^{n-1}$ the theorem is valid. For an arbitrary $\mathbb{Q}$-basis $\omega_1, \ldots, \omega_n$ there exists a matrix $M \in \text{GL}_n(\mathbb{Q})$ such that

$$
\begin{pmatrix}
\omega_1 \\
\omega_2 \\
\vdots \\
\omega_n
\end{pmatrix}
= M
\begin{pmatrix}
1 \\
\alpha \\
\vdots \\
\alpha^{n-1}
\end{pmatrix}.
$$

Applying the homomorphisms $\varphi : F \to \mathbb{C}$ one obtains the following equality of $n \times n$ matrices:

$$(\varphi(\omega_i))_{\varphi, i} = M \cdot (\varphi(\alpha^i))_{\varphi, i},$$

and therefore

$$\det((\varphi(\omega_i))_{\varphi, i}) = \det(M) \cdot \det((\varphi(\alpha^i))_{\varphi, i}) \neq 0,$$

as required. This proves the proposition. \hfill \square

The number field $\mathbb{Q}$ admits a unique embedding into the field of complex numbers $\mathbb{C}$. The image of this embedding is contained in $\mathbb{R}$. In general, a number field $F$ admits several embeddings in $\mathbb{C}$, and the images of these embeddings are not necessarily contained in $\mathbb{R}$. We generalize the embedding $\Phi : \mathbb{Q} \to \mathbb{R}$ as follows.

Let $F$ be a number field and let $\alpha \in F$ be a primitive element, i.e., an element such that $F = \mathbb{Q}(\alpha)$. In other words $F = \mathbb{Q}[T]/(f(T))$ where $f(T)$ denotes the minimum polynomial of $\alpha$ over $\mathbb{Q}$. Let $n = \deg(f) = [F : \mathbb{Q}]$. We put

$$F \otimes \mathbb{R} = \mathbb{R}[T]/(f(T)).$$

In these notes, $F \otimes \mathbb{R}$ is just our notation for the $\mathbb{R}$-algebra $\mathbb{R}[T]/(f(T))$. This algebra is actually the tensor product of $F$ over $\mathbb{Q}$ with $\mathbb{R}$ and this also shows that the construction does not depend on the choice of $\alpha$, but we will not use this interpretation. The natural map $\mathbb{Q}[T]/(f(T)) \to \mathbb{R}[T]/(f(T))$ gives us a map

$$\Phi : F \to F \otimes \mathbb{R}.$$ 

We compute the ring $F \otimes \mathbb{R}$ explicitly: Since $\mathbb{C}$ is an algebraically closed field, the polynomial $f(T) \in \mathbb{Q}[T]$ factors completely over $\mathbb{C}$. Let’s say it has precisely $r_1$ real zeroes $\beta_1, \ldots, \beta_{r_1}$ and $r_2$ pairs of complex conjugate zeroes $\gamma_1, \bar{\gamma}_1, \ldots, \gamma_{r_2}, \bar{\gamma}_{r_2}$. We have

$$r_1 + 2r_2 = n.$$
The numbers $r_1$ and $r_2$ depend only on the number field $F$ and not on the choice of $\alpha$. By the Chinese Remainder Theorem there is an isomorphism

$$F \otimes \mathbb{R} \xrightarrow{\sim} \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$$

given by $T \mapsto (\beta_1, \ldots, \beta_{r_1}, \gamma_1, \ldots, \gamma_{r_2})$. Identifying the spaces $F \otimes \mathbb{R}$ and $\mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$ by means of this isomorphism, we obtain an explicit description of the map $\Phi$ as follows.

**Definition 2.5.** Let $F$ be a number field. With the notation above, the map

$$\Phi: F \longrightarrow \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$$

is defined by

$$\Phi(x) = (\varphi_1(x), \ldots, \varphi_{r_1}(x), \varphi_{r_1+1}(x), \ldots, \varphi_{r_1+r_2}(x))$$

where the $\varphi_i: F \to \mathbb{C}$ are determined by $\varphi_i(\alpha) = \beta_i$ for $1 \leq i \leq r_1$ and $\varphi_{r_1+i}(\alpha) = \gamma_i$ for $1 \leq i \leq r_2$.

For completeness sake we define $\varphi_{r_1+r_2+i}(\alpha) = \gamma_i$ for $1 \leq i \leq r_2$. The map $\Phi$ is not canonical: replacing $\gamma_i$ by $\gamma_i$ would give a different map $\Phi$. This ambiguity is not important in the sequel.

**Example.** Let $\alpha = \sqrt{2}$ be a zero of $T^4 - 2 \in \mathbb{Q}[T]$ and let $F = \mathbb{Q}(\alpha)$. The minimum polynomial of $\alpha$ is $T^4 - 2$. It has two real roots $\pm \sqrt{2}$ and two complex conjugate roots $\pm i \sqrt{2}$. We conclude that $r_1 = 2$ and $r_2 = 1$. The homomorphisms $\varphi_i: F \to \mathbb{C}$ are determined by

$$\begin{align*}
\varphi_1(\alpha) &= \sqrt{2}, \\
\varphi_2(\alpha) &= -\sqrt{2}, \\
\varphi_3(\alpha) &= i \sqrt{2}, \\
\varphi_4(\alpha) &= -i \sqrt{2}.
\end{align*}$$

The map

$$\Phi: F \longrightarrow F \otimes \mathbb{R} = \mathbb{R} \times \mathbb{R} \times \mathbb{C}$$

is given by

$$\Phi(x) = (\varphi_1(x), \varphi_2(x), \varphi_3(x)).$$

**Theorem 2.6.** Let $F$ be a number field of degree $n$.

(i) The map $\Phi: F \to F \otimes \mathbb{R}$ maps a $\mathbb{Q}$-basis of $F$ to an $\mathbb{R}$-basis of $F \otimes \mathbb{R}$.

(ii) The map $\Phi$ is injective.

(iii) The image $\Phi(F)$ is a dense subset in the vector space $F \otimes \mathbb{R} = \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$, equipped with the usual Euclidean topology.

**Proof.** (i) We identify the real vectorspace $\mathbb{C}$ with $\mathbb{R}^2$ by means of the usual correspondence

$$z \leftrightarrow (\text{Re}(z), \text{Im}(z)).$$

Let $\omega_1, \ldots, \omega_n$ be a $\mathbb{Q}$-basis of $F$. Then

$$\Phi(\omega_i) = \left(\ldots, \varphi_k(\omega_i), \ldots, \text{Re}(\varphi_l(\omega_i)), \text{Im}(\varphi_l(\omega_i)), \ldots\right),$$

where $k$ and $l$ are chosen so that $\varphi_k(\omega_i) = \beta_i$ and $\varphi_l(\omega_i) = \gamma_i$.
where \( k \) denotes a “real” index whenever \( 1 \leq k \leq r_1 \) and \( l \) denotes a “complex” index whenever \( r_1 + 1 \leq l \leq r_1 + r_2 \). We put the vectors \( \Phi(\omega_i) \) in an \( n \times n \)-matrix:

\[
\Phi \begin{pmatrix}
\omega_1 \\
\omega_2 \\
\vdots \\
\omega_n
\end{pmatrix} = 
\begin{pmatrix}
\varphi_k(\omega_1) & \text{Re}(\varphi_1(\omega_1)) & \text{Im}(\varphi_1(\omega_1)) & \cdots \\
\varphi_k(\omega_2) & \text{Re}(\varphi_2(\omega_2)) & \text{Im}(\varphi_2(\omega_2)) & \cdots \\
\vdots & \vdots & \vdots & \ddots \\
\varphi_k(\omega_n) & \text{Re}(\varphi_n(\omega_n)) & \text{Im}(\varphi_n(\omega_n)) & \cdots
\end{pmatrix}
\]

The first \( r_1 \) columns correspond to the homomorphisms \( \varphi_k : F \to \mathbb{R} \) and the remaining \( 2r_2 \) correspond to the real and imaginary parts of the \( r_2 \) non-conjugate homomorphisms \( \varphi_1 : F \to \mathbb{C} \). Using the formula \( \text{Re}(z) = (z + \bar{z})/2 \) and \( \text{Im}(z) = (z - \bar{z})/2i \) one sees that the determinant of this matrix is equal to

\[
(2i)^{-r_2} \cdot \det (\varphi_k(\omega_j))_{k,j}.
\]

By Prop. 2.4 its value is different from zero. Therefore the \( \Phi(\omega_i) \) form an \( \mathbb{R} \)-basis for \( F \otimes \mathbb{R} \).

(ii) Let \( x \in F \) and \( \Phi(x) = 0 \). This implies, in particular, that \( \varphi_1(x) = 0 \). Since \( \varphi_1 \) is a homomorphism of fields, it is injective and we conclude that \( x = 0 \), as required.

(iii) The image of \( \Phi \) is a \( \mathbb{Q} \)-vector space and it contains an \( \mathbb{R} \)-basis by part (i). Therefore it is dense. \( \square \)

**Example 2.7.** (Cyclotomic fields) For any \( m \in \mathbb{Z}_{\geq 1} \) we define the \( m \)-th cyclotomic polynomial \( \Phi_m(T) \in \mathbb{Z}[T] \) in the following inductive manner:

\[
T^m - 1 = \prod_{d|m} \Phi_d(T).
\]

Alternatively

\[
\Phi_m(T) = \prod_{k \in (\mathbb{Z}/m\mathbb{Z})^*} T - \exp(2\pi ik/m).
\]

The degree of \( \Phi_m \) is \( \varphi(m) \), where \( \varphi(m) = \#(\mathbb{Z}/m\mathbb{Z})^* \) is Euler’s \( \varphi \)-function. See Exercise 2.K. It is rather easy to show that \( \Phi_m \) is irreducible over \( \mathbb{Q} \) when \( m \) is a power of a prime number, but the general case is more delicate. We give the proof here:

**Proposition 2.8.** The cyclotomic polynomial \( \Phi_m(T) \) is irreducible in \( \mathbb{Q}[T] \).

**Proof.** Let \( g(T) \in \mathbb{Q}[T] \) be a monic irreducible factor of \( \Phi_m(T) \) and write \( T^m - 1 = g(T)h(T) \). By Gauß’s Lemma, \( g(T) \) and \( h(T) \) are in \( \mathbb{Z}[T] \). Suppose \( \alpha \in \mathbb{C} \) is a zero of \( g \). Then \( \alpha \) is a zero of \( T^m - 1 \). Let \( p \) be a prime not dividing \( m \). Then \( \alpha^p \) is also a zero of \( T^m - 1 \). If \( g(\alpha^p) \neq 0 \), then \( h(\alpha^p) = 0 \) and therefore \( g(T) \) divides \( h(T^p) \). This implies that \( g(T) \) divides \( h(T^p) \) in the ring \( \mathbb{F}_p[T] \). Let \( \varphi(T) \) denote an irreducible divisor of \( g(T) \) in \( \mathbb{F}_p[T] \). Then \( 
\varphi(T) \) divides both \( g(T) \) and \( h(T) \) modulo \( p \). This implies that \( T^m - 1 \) has a double zero mod \( p \). But this is impossible because the derivative \( mT^{m-1} \) has, since \( m \neq 0 \) (mod \( p \)), no zeroes in common with \( T^m - 1 \).

Therefore \( g(\alpha^p) = 0 \). We conclude that for every prime \( p \) not dividing \( m \) and every \( \alpha \in \mathbb{C} \) with \( f(\alpha) = 0 \), one has that \( g(\alpha^p) = 0 \). This implies that \( g(\alpha^k) = 0 \) for every integer \( k \) which is coprime to \( m \). This shows that \( \Phi_m(T) \) and \( g(T) \) have the same zeroes and hence that \( \Phi_m(T) = g(T) \) is irreducible. This proves the proposition. \( \square \)

We conclude that the cyclotomic fields \( \mathbb{Q}[X]/(\Phi_m(X)) \) are number fields of degree \( \varphi(m) \). Usually one writes \( \mathbb{Q}(\zeta_m) \) for these fields; here \( \zeta_m \) denotes a zero of \( \Phi_m(T) \), i.e., a primitive \( m \)-th root of unity.
Exercises

(2.A) Compute the degrees of the number fields

\[ \mathbb{Q}(\sqrt{2}, \sqrt{-6}), \mathbb{Q}(\sqrt{-2}, 1 + 2\sqrt{3}, \sqrt{-6}), \text{ and } \mathbb{Q}(\sqrt{2} + 3\sqrt{3}). \]

(2.B) Find an element \( \alpha \in F = \mathbb{Q}(\sqrt{3}, \sqrt{-5}) \) such that \( F = \mathbb{Q}(\alpha) \).

(2.C) Let \( p \) be a prime. Compute the minimum polynomial of a primitive \( p \)-th root of unity \( \zeta_p \). Show that \([\mathbb{Q}(\zeta_p) : \mathbb{Q}] = p - 1\).

(2.D) Let \( \varphi : \mathbb{Q} \to \mathbb{C} \) be a field homomorphism. Show that \( \varphi(q) = q \) for every \( q \in \mathbb{Q} \).

(2.E) (Vandermonde) Let \( R \) be a commutative ring and let \( \alpha_1, \alpha_2, \ldots, \alpha_n \in R \). Show that

\[
\det\begin{pmatrix}
1 & 1 & \cdots & 1 \\
\alpha_1 & \alpha_2 & \cdots & \alpha_n \\
\alpha_1^2 & \alpha_2^2 & \cdots & \alpha_n^2 \\
\vdots & \vdots & \ddots & \vdots \\
\alpha_1^{n-1} & \alpha_2^{n-1} & \cdots & \alpha_n^{n-1}
\end{pmatrix} = \prod_{1 \leq i < j \leq n} (\alpha_j - \alpha_i).
\]

(2.F) Consider the extension \( L = \mathbb{F}_p(\sqrt[3]{X}, \sqrt[3]{Y}) \) of the field \( K = \mathbb{F}_p(X, Y) \). Show that the theorem of the primitive element does not hold in this case. (Why does the argument of 2.2 not work in this case?) Show that there are infinitely many distinct fields \( F \) with \( K \subset C \subset L \).

(2.G) Let \( K \) be a finite extension of degree \( n \) of a finite field \( \mathbb{F}_q \). Show:

(i) there exists \( \alpha \in K \) such that \( K = \mathbb{F}_q(\alpha) \);
(ii) there are precisely \( n \) distinct embeddings \( \varphi_i : K \to \mathbb{F}_q \) which induce the identity map on \( \mathbb{F}_q \).

(2.H) Let \( F = \mathbb{Q}(\sqrt[-3]{3}) \). Give explicitly the homomorphism \( \Phi : F \to F \otimes \mathbb{R} \) as in Definition 2.5.

(2.I) Find a \( \mathbb{Q} \)-basis for \( \mathbb{Q}(\sqrt{2}, \sqrt{-1}) \) and \( \mathbb{Q}(\sqrt{2}, \zeta_3) \).

(2.J) Let \( F \) be a number field with \( r_1 \geq 1 \), i.e., \( F \) admits an embedding into \( \mathbb{R} \). Show that the only roots of unity in \( F \) are \( \pm 1 \).

(2.K) Let \( \Phi_m \) denote the \( m \)-th cyclotomic polynomial.

(i) Show that

\[ \Phi_m(T) = \prod_{k \in \{\mathbb{Z}/m\mathbb{Z}\}^*} (T - e^{2\pi ik/m}). \]

(ii) Show that

\[
\begin{align*}
\Phi_1(T) &= T - 1, \\
\Phi_2(T) &= T + 1, \\
\Phi_3(T) &= T^2 + T + 1, \\
\Phi_4(T) &= T^2 + 1, \\
\Phi_5(T) &= T^4 + T^3 + T^2 + T + 1, \\
\Phi_6(T) &= T^2 - T + 1, \\
\Phi_7(T) &= T^6 + T^5 + T^4 + T^3 + T^2 + T + 1, \\
\Phi_8(T) &= T^4 + 1, \\
\Phi_9(T) &= T^6 + T^3 + 1, \\
\Phi_{10}(T) &= T^4 - T^3 + T^2 - T + 1.
\end{align*}
\]

(iii) Show that \( \Phi_m(T) \in \mathbb{Z}[T] \) for every \( m \).

(iv) Show that \( \deg(\Phi_m) = \varphi(m) \) where \( \varphi(m) = \#(\mathbb{Z}/m\mathbb{Z})^* \) denotes the \( \varphi \)-function of Euler.

(v) Let \( l \) be a prime and let \( k \geq 1 \). Show that

\[ \Phi_{lk}(T) = T^{l^{k-1}(l-1)} + T^{l^{k-1}(l-2)} + \cdots + T^{l^{k-1}} + 1. \]

13
Show that $\Phi_{1,k}(S + 1)$ is an Eisenstein polynomial with respect to $l$. Conclude it is irreducible over $\mathbb{Q}$.

(2.L) Let $m \geq 1$ be an integer. Compute the numbers $r_1$ and $r_2$ associated to $F = \mathbb{Q}(\zeta_m)$ in Def. 2.5.
Chapter 3. Norms, traces and discriminants.

In this chapter we introduce the characteristic polynomial of an element, its norm and its trace. We define the discriminant of an $n$-tuple of elements in a number field of degree $n$.

Let $F$ be a number field of degree $n$ and let $x \in F$. Multiplication by $x$ is a $\mathbb{Q}$-linear map $M_x: F \to F$. With respect to a $\mathbb{Q}$-basis of $F$, one can view $M_x$ as an $n \times n$-matrix with rational coefficients.

**Definition 3.1.** Let $F$ be a number field of degree $n$ and let $x \in F$. The characteristic polynomial $f^x_{\text{char}}(T) \in \mathbb{Q}[T]$ of $x$ is

$$f^x_{\text{char}}(T) = \det(T \cdot \text{Id} - M_x).$$

We have $f^x_{\text{char}}(T) = T^n + a_{n-1}T^{n-1} + \cdots + a_1T + a_0$ with $a_i \in \mathbb{Q}$. The norm $N(x)$ and the trace $\text{Tr}(x)$ of $x$ are defined by

$$N(x) = \det(M_x) = (-1)^n a_0,$$

$$\text{Tr}(x) = \text{Trace}(M_x) = -a_{n-1}.$$

It is immediate from the definitions that $\text{Tr}(x)$ and $N(x)$ are rational numbers. They are well defined, because the characteristic polynomial, the norm and the trace of $x$ do not depend on the basis with respect to which the matrix $M_x$ has been defined. One should realize that the characteristic polynomial $f^x_{\text{char}}(T)$, and therefore the norm $N(x)$ and the trace $\text{Tr}(x)$ depend on the field $F$ in which we consider $x$ to be! We don’t write $\text{Tr}_F(x)$ or $N_F(x)$ in order not to make the notation too cumbersome. The norm and the trace have the following, usual properties:

$$N(xy) = N(x)N(y),$$

$$\text{Tr}(x + y) = \text{Tr}(x) + \text{Tr}(y)$$

for $x, y \in F$.

**Example.** Let $F = \mathbb{Q}(\sqrt{2})$ and let $x = \sqrt{2} = (\sqrt{2})^2 \in F$. We take $\{1, \sqrt{2}, \sqrt{2}, (\sqrt{2})^3\}$ as a $\mathbb{Q}$-basis of $F$. With respect to this basis, the multiplication by $x$ is given by the matrix

$$M_x = \begin{pmatrix}
0 & 0 & 2 & 0 \\
0 & 0 & 0 & 2 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0
\end{pmatrix}. $$

It is easily verified that the characteristic polynomial of $x$ is $f^x_{\text{char}}(T) = T^4 - 4T^2 + 4$, its norm is $N(x) = 4$ and its trace is $\text{Tr}(x) = 0$. If we consider, on the other hand, $x = \sqrt{2}$ in $F = \mathbb{Q}(\sqrt{2})$, then the characteristic polynomial of $x = \sqrt{2}$ is $f^x_{\text{char}}(T) = T^2 - 2$, its norm $N(x) = 2$ and its trace $\text{Tr}(x) = 0$.

**Proposition 3.2.** Let $F$ be a number field of degree $n$ and let $x \in F$.

(i) We have

$$f^x_{\text{char}}(T) = \prod_{\varphi: F \to \mathbb{C}} (T - \varphi(x)).$$

(ii) We have

$$f^x_{\text{char}}(T) = f^x_{\text{min}}(T)^{[F: \mathbb{Q}(x)]}.$$
(iii) One has \[ N(x) = \prod_{\varphi} \varphi(x) \] and \[ \text{Tr}(x) = \sum_{\varphi} \varphi(x), \] where the product and the sum run over all \( n \) embeddings \( \varphi : F \to \mathbb{C} \).

**Proof.** (i) We have the following commutative diagram:

\[
\begin{array}{ccc}
F & \xrightarrow{\Phi} & \mathbb{R}^n \times \mathbb{C}^s \\
\downarrow x & & \downarrow \left( \varphi_1(x), \ldots, \varphi_{r_1 + r_2}(x) \right) \\
F & \xrightarrow{\Phi} & \mathbb{R}^n \times \mathbb{C}^s
\end{array}
\]

where the right vertical arrow is given by multiplication by \( \varphi_i(x) \) on the \( i \)-th coordinate of \( F \oplus \mathbb{R} = \mathbb{R}^n \times \mathbb{C}^s \).

By Theorem 2.6(i), the image of any \( \mathbb{Q} \)-basis of \( F \) under \( \Phi \) is an \( \mathbb{R} \)-basis. When we write the linear map on the left as a matrix with respect to such a basis, we obtain the matrix \( M_x \). Next we write the map on the right in matrix form. When we do this with respect to the canonical \( \mathbb{R} \)-basis of \( \mathbb{R}^n \times \mathbb{C}^s \), we find a matrix which is diagonal as far as the “real” coordinates are concerned. If the \( i \)-th coordinate is “complex”, we identify \( \mathbb{C} \) with \( \mathbb{R}^2 \) via \( z \leftrightarrow (\text{Re}(z), \text{Im}(z)) \). In this way, the multiplication by \( \varphi_i(x) \) can be represented by a \( 2 \times 2 \)-matrix

\[
\begin{pmatrix}
\text{Re}\varphi_i(x) & \text{Im}\varphi_i(x) \\
-\text{Im}\varphi_i(x) & \text{Re}\varphi_i(x)
\end{pmatrix}
\]

with eigenvalues \( \varphi_i(x) \) and \( \varphi_{r_1+i}(x) = \overline{\varphi_i(x)} \). Altogether we find an \( n \times n \)-matrix with eigenvalues the \( \varphi_i(x) \) for \( 1 \leq i \leq n \). Therefore the characteristic polynomial is \( \prod_{i=1}^{n}(T - \varphi_i(x)) \). Since the characteristic polynomial of \( M_x \) does not depend on the basis, the result follows.

(ii) Let \( g(T) \in \mathbb{Q}[T] \) be an irreducible divisor of \( f^x_{\text{char}}(T) \). We conclude from (i) that \( g(T) \) has one of the \( \varphi_i(x) \) as a zero. Since \( g \) has rational coefficients, we have that

\[ \varphi_i(g(x)) = g(\varphi_i(x)) = 0. \]

Since \( \varphi_i \) is injective it follows that \( g(x) = 0 \). Therefore \( f^x_{\text{min}} \) divides \( g \) and by the irreducibility of \( g \) we conclude that \( g = f^x_{\text{min}} \). Since \( g \) was an arbitrary irreducible divisor of the characteristic polynomial, it follows that \( f^x_{\text{char}}(T) \) is a power of \( f^x_{\text{min}}(T) \). Finally, the degree of \( f^x_{\text{char}} \) is \( n = [F : \mathbb{Q}] \) and the degree of \( f^x_{\text{min}} \) is \( [\mathbb{Q}(x) : \mathbb{Q}] \). This easily implies (ii).

(iii) This is immediate from (i). \( \Box \)

Next we introduce *discriminants*.

**Definition 3.3.** Let \( F \) be a number field of degree \( n \) and let \( \omega_1, \omega_2, \ldots, \omega_n \in F \). We define the discriminant \( \Delta(\omega_1, \omega_2, \ldots, \omega_n) \in \mathbb{Q} \) by

\[ \Delta(\omega_1, \omega_2, \ldots, \omega_n) = \det \left( \text{Tr}(\omega_i \omega_j)_{1 \leq i, j \leq n} \right). \]

The discriminant depends only on the set \( \{\omega_1, \omega_2, \ldots, \omega_n\} \), and not on the order of the elements. The basic properties of discriminants are contained in the following proposition.

**Proposition 3.4.** Let \( F \) be a number field of degree \( n \) and let \( \omega_1, \omega_2, \ldots, \omega_n \in F \).

(i) We have

\[ \Delta(\omega_1, \omega_2, \ldots, \omega_n) = \det (\varphi(\omega_i))^2_{i, \varphi} \in \mathbb{Q}. \]

(ii) We have \( \Delta(\omega_1, \omega_2, \ldots, \omega_n) \neq 0 \) if and only if \( \omega_1, \omega_2, \ldots, \omega_n \) is a basis for \( F \) as a vector space over \( \mathbb{Q} \).
(iii) If \( \omega_i' = \sum_{j=1}^{n} \lambda_{ij} \omega_j \) with \( \lambda_{ij} \in \mathbb{Q} \) for \( 1 \leq i, j \leq n \), then

\[
\Delta(\omega_1', \omega_2', \ldots, \omega_n') = \det(\lambda_{ij})^2 \cdot \Delta(\omega_1, \omega_2, \ldots, \omega_n).
\]

**Proof.** (i) The determinant is rational, because its entries are traces of elements in \( F \) and therefore rational numbers. From Prop. 3.2(iii) one deduces the following equality of \( n \times n \) matrices:

\[
\begin{pmatrix}
\varphi_1(\omega_1) & \varphi_2(\omega_1) & \cdots & \varphi_1(\omega_1) \\
\varphi_1(\omega_2) & \varphi_2(\omega_2) & \cdots & \varphi_1(\omega_2) \\
\varphi_1(\omega_3) & \varphi_2(\omega_3) & \cdots & \varphi_1(\omega_3) \\
\vdots & \vdots & \ddots & \vdots
\end{pmatrix}
\cdot
\begin{pmatrix}
\varphi_1(\omega_1) & \varphi_1(\omega_2) & \cdots & \varphi_1(\omega_1) \\
\varphi_2(\omega_2) & \varphi_2(\omega_2) & \cdots & \varphi_2(\omega_2) \\
\varphi_3(\omega_3) & \varphi_3(\omega_3) & \cdots & \varphi_3(\omega_3) \\
\vdots & \vdots & \ddots & \vdots
\end{pmatrix}
= \begin{pmatrix}
\text{Tr}(\omega_1^2) & \text{Tr}(\omega_1\omega_2) & \cdots & \text{Tr}(\omega_1) \\
\text{Tr}(\omega_1\omega_2) & \text{Tr}(\omega_2^2) & \cdots & \text{Tr}(\omega_1) \\
\text{Tr}(\omega_1\omega_3) & \text{Tr}(\omega_2\omega_3) & \cdots & \text{Tr}(\omega_2) \\
\vdots & \vdots & \ddots & \vdots
\end{pmatrix},
\]

and (i) follows easily.

(ii) Immediate from Prop. 2.4.

(iii) We have the following product of \( n \times n \) matrices

\[
(\lambda_{i,j} \cdot (\varphi_j(\omega_k)))_{i,k} = (\varphi_i(\omega_k))_{i,k},
\]

and with this identity (iii) readily follows from (i). \( \square \)

In the sequel we will calculate several discriminants. Therefore we briefly recall the relation between discriminants in the sense of Def. 3.3 and discriminants and resultants of polynomials.

Let \( K \) be a field, let \( b, c \in K^* \) and let \( \beta_1, \beta_2, \ldots, \beta_r \in K \) and \( \gamma_1, \gamma_2, \ldots, \gamma_s \in K \). Put

\[
g(T) = b \cdot \prod_{i=1}^{r} (T - \beta_i) \quad \text{and} \quad h(T) = c \cdot \prod_{i=1}^{s} (T - \gamma_i).
\]

The resultant \( \text{Res}(g, h) \) of \( g \) and \( h \) is defined by

\[
\text{Res}(g, h) = b^s c^r \cdot \prod_{i=1}^{r} \prod_{j=1}^{s} (\beta_i - \gamma_j) = b^s \cdot \prod_{i=1}^{r} h(\beta_i) \cdot (-1)^{r^s} c^r \cdot \prod_{j=1}^{s} g(\gamma_j).
\]

Resultants can be calculated efficiently by means of an algorithm, which is very similar to the Euclidean algorithm in the polynomial ring \( K[T] \). See Exercise 3.K for details.

Discriminants of polynomials can be expressed in terms of certain resultants. Let \( \alpha_1, \ldots, \alpha_n \in K \). Let \( f(T) = \prod_{i=1}^{n} (T - \alpha_i) \in K[T] \). The discriminant \( \text{Disc}(f) \) of \( f \) is defined by

\[
\text{Disc}(f) = \prod_{1 \leq i < j \leq n} (\alpha_i - \alpha_j)^2.
\]

By differentiating the relation \( f(T) = \prod_{j=1}^{n} (T - \alpha_j) \) and substituting \( T = \alpha_i \) one finds that \( f'(\alpha_i) = \prod_{j \neq i} (\alpha_i - \alpha_j) \) and one deduces easily that

\[
\text{Disc}(f) = (-1)^{\frac{n(n-3)}{2}} \cdot \text{Res}(f, f').
\]

**Proposition (3.5).** Let \( F \) be a number field of degree \( n \). Let \( \alpha \in F \) and let \( f = f_{\text{char}} \) denote its characteristic polynomial. Then

\[
\Delta(1, \alpha, \ldots, \alpha^{n-1}) = \text{Disc}(f) = (-1)^{\frac{n(n-3)}{2}} \text{N}(f'(\alpha)) = (-1)^{\frac{n(n-3)}{2}} \text{Res}(f, f').
\]
Proof. The first equality follows from Prop. 3.4(i) and the Vandermonde determinant in Exercise 2.E. The second follows by differentiating both sides of the equation \( f(T) = \prod_{j=1}^{n}(T - \varphi_j(\alpha)) \), substituting \( \varphi_i(\alpha) \) for \( T \) and applying Prop. 3.2(iii). The third equality has just been explained. \( \square 

\textbf{Exercises}

(3.A) Let \( F \) be a number field of degree \( n \) and let \( x \in F \). Show that for \( q \in \mathbb{Q} \subset F \) one has that

\[
\text{Tr}(qx) = q\text{Tr}(x), \\
\text{Tr}(q) = nq, \\
N(q) = q^n.
\]

Show that the map \( \text{Tr}: F \to \mathbb{Q} \) is surjective. Show that the norm \( N: F^* \to \mathbb{Q}^* \) is, in general, not surjective.

(3.B) Let \( F \) be a number field of degree \( n \) and let \( \alpha \in F \). Show that for \( q \in \mathbb{Q} \) one has that \( N(q - \alpha) = f_{\text{char}}^a(q) \). Show that for \( q, r \in \mathbb{Q} \) one has that \( N(q - r\alpha) = r^n f_{\text{char}}^a(q/r) \).

(3.C) Let \( \alpha = \zeta_5 + \zeta_5^{-1} \in \mathbb{Q}(\zeta_5) \) where \( \zeta_5 \) denotes a primitive 5th root of unity. Calculate the characteristic polynomial of \( \alpha \in \mathbb{Q}(\zeta_5) \).

(3.D) Prove that \( \text{Disc}(T^n - a) = n^n a^{n-1} \). Compute \( \text{Disc}(T^2 + bT + c) \) and \( \text{Disc}(T^3 + bT + c) \).

(3.E) Let \( f(T) = T^3 - T + 1 \in \mathbb{Z}[T] \). Show that \( f \) is irreducible. Determine \( r_1, r_2 \) and the discriminant of \( f \).

(3.F) Consider the field \( \mathbb{Q}(\sqrt{3}, \sqrt{5}) \). Compute \( \Delta(1, \sqrt{3}, \sqrt{5}, \sqrt{15}) \) and \( \Delta(1, \sqrt{3}, \sqrt{5}, \sqrt{3 + \sqrt{5}}) \).

(3.G) Let \( K \) be a field and let \( f \in K[T] \). Show that \( f \) has a double zero if and only if \( \text{Disc}(f) = 0 \). Let \( h \in \mathbb{Z}[T] \) be a monic polynomial. Show that it has a double zero modulo a prime \( p \) if and only if \( p \) divides \( \text{Disc}(f) \).

(3.H) Let \( F \) be a number field of degree \( n \). Let \( \alpha \in F \). Show that

\[
\Delta(1, \alpha, \ldots, \alpha^{n-1}) = \det((p_{i+j-2})_{1 \leq i, j \leq n}).
\]

Here \( p_k \) denotes the power sum \( \varphi_1(\alpha)^k + \cdots + \varphi_n(\alpha)^k \). The \( \varphi_i \) denote the embeddings \( F \hookrightarrow \mathbb{C} \).

(3.I) (Newton’s formulas) Let \( K \) be a field and let \( \alpha_1, \alpha_2, \ldots, \alpha_n \in K \). We define the symmetric functions \( s_k \) of the \( \alpha_i \) by

\[
\prod_{i=1}^{n}(T - \alpha_i) = T^n - s_1 T^{n-1} + s_2 T^{n-2} + \cdots + (-1)^n s_n.
\]

We extend the definition by putting \( s_k = 0 \) whenever \( k > n \). We define the power sums \( p_k \) by

\[
p_k = \sum_{i=1}^{n} \alpha_i^k \quad \text{for} \ k \geq 0.
\]

Show that for every \( k \geq 1 \) one has that

\[
(-1)^k k s_k = p_k - p_{k-1} s_1 + p_{k-2} s_2 - p_{k-3} s_3 + \cdots.
\]

In particular

\[
\begin{align*}
1 s_1 &= p_1 \\
-2 s_2 &= p_2 - p_1 s_1 \\
3 s_3 &= p_3 - p_2 s_1 + p_1 s_2 \\
-4 s_4 &= p_4 - p_3 s_1 + p_2 s_2 - p_1 s_3 \\
5 s_5 &= \ldots
\end{align*}
\]
(Hint: Take the logarithmic derivative of $\prod_{i=1}^{n}(1-\alpha_iT).$)

(3.J) Show that the polynomial $T^6 + T^3 - 2T + 1 \in \mathbb{Z}[T]$ is irreducible. Compute its discriminant. (Hint: use Prop. 3.5)

(3.K) (Results) Let $K$ be a field and let $\alpha_1, \ldots, \alpha_r \in K$. Put $g = b \prod_{i=1}^{r}(T-\alpha_i)$ and let $h, h' \in K[T]$ be non-zero polynomials of degree $s$ and $s'$ respectively. Suppose that $h \equiv h' \pmod{g}$.

(i) Show that $\text{Res}(g, h) = (-1)^s \text{Res}(h, g)$.

(ii) Show that $\text{Res}(g, h) = b^s \prod_{\alpha : g(\alpha) = 0} h(\alpha)$.

(iii) Show that $b^s \text{Res}(g, h) = b^s \text{Res}(g, h')$

(iv) Using parts (i) and (ii), design an efficient algorithm, similar to the Euclidean algorithm in the ring $K[T]$, to calculate resultants of polynomials.

(3.L) Let $F_q$ be a finite field with $q$ elements. Let $K$ be a finite extension of $F_q$ and let $\omega_1, \omega_2, \ldots, \omega_n \in K$. Show that the discriminant $\Delta(\omega_1, \ldots, \omega_n) = \det(\text{Tr}(\omega_j \omega_k))_{i,j}$ is not zero if and only if $\omega_1, \ldots, \omega_n$ is an $F_q$-basis for $K$. Here the definition of the trace $\text{Tr}(\alpha)$ of an element $\alpha \in K$ is similar to Def. 3.1. (Hint: copy the proof of Prop. 3.4)

(3.M) For $n \in \mathbb{Z}_{\geq 1}$ let $\mu(n)$ denote the Möbius function:

$$
\mu(n) = \begin{cases} 
(-1)^m & \text{when } n \text{ is squarefree with precisely } m \text{ prime factors}, \\
0 & \text{otherwise.}
\end{cases}
$$

(i) Let $\varphi(n)$ denote Euler’s $\varphi$-function. Prove that for $n \geq 1$ one has $\sum_{d|n} d\mu(n/d) = \varphi(n)$.

(ii) Show that

$$
\sum_{d|n} \mu(d) = \begin{cases} 
1 & \text{if } n = 1, \\
0 & \text{otherwise.}
\end{cases}
$$

(iii) Show that

$$
\Phi_n(T) = \prod_{d|n} (T^d - 1)^\mu(n/d)
$$

for every integer $n \geq 1$.

(3.N) The goal of this exercise is to compute the discriminant of the cyclotomic polynomial $\Phi_m(T)$.

(i) Let $\zeta$ denote a primitive $m$-th root of unity. Prove that

$$
\Phi_m(\zeta) \prod_{d|m, d \neq m} (\zeta^d - 1)^{-\mu(m/d)} = m\zeta^{-1}.
$$

(Hint: write $T^m - 1 = \Phi_m(T)G(T)$, differentiate and put $T = \zeta$.)

(ii) Show that

$$
\prod_{d|m, d \neq m} (\zeta^d - 1)^{-\mu(m/d)} = \prod_{p|m} (\zeta_p - 1)
$$

where $\zeta_p = \zeta^m/p$; it is a primitive $p$-th root of unity in $\mathbb{Q}(\zeta_m)$.

(iii) For $m \geq 3$ show that

$$
\text{Disc}(\Phi_m(T)) = (-1)^{\varphi(m)} \left( \frac{m}{\prod_{p|m} p^{\frac{1}{p-1}}} \right)^{\varphi(m)}.
$$

(Hint: use Prop. 3.5.)
Chapter 4. Rings of integers.

In Chapter 2 we have introduced number fields as finite extensions of \( \mathbb{Q} \). A number field \( F \) admits a natural embedding \( \Phi \) into the finite dimensional \( \mathbb{R}\)-algebra \( F \otimes \mathbb{R} \); this is seen as a generalization of the embedding \( \mathbb{Q} \hookrightarrow \mathbb{R} \). In this chapter we generalize the subring of integers \( \mathbb{Z} \) of \( \mathbb{Q} \): every number field \( F \) contains a subring \( O_F \) of integral elements.

**Definition 4.1.** Let \( F \) be a number field. An element \( x \in F \) is called integral if there exists a monic polynomial \( f(T) \in \mathbb{Z}[T] \) with \( f(x) = 0 \). The set of integral elements of \( F \) is denoted by \( O_F \).

It is clear that the integrality of an element does not depend on the field \( F \) it contains. An example of an integral element is \( i = \sqrt{-1} \), since it is a zero of the monic polynomial \( T^2 + 1 \in \mathbb{Z}[T] \).

Every \( n \)-th root of unity is integral, since it is a zero of \( T^n - 1 \). All ordinary integers \( n \in \mathbb{Z} \) are integral in this new sense because they are zeroes of the polynomials \( T - n \).

**Lemma 4.2.** Let \( F \) be a number field and let \( x \in F \). The following are equivalent

(i) \( x \) is integral.

(ii) The minimum polynomial \( f_{\text{min}}^x(T) \) of \( x \) over \( \mathbb{Q} \) is in \( \mathbb{Z}[T] \).

(iii) The characteristic polynomial \( f_{\text{char}}(T) \) of \( x \) over \( \mathbb{Q} \) is in \( \mathbb{Z}[T] \).

(iv) There exists a finitely generated additive subgroup \( M \neq 0 \) of \( F \) such that \( xM \subset M \).

**Proof.** (i) \( \Rightarrow \) (ii) Let \( x \) be integral and let \( f(T) \in \mathbb{Z}[T] \) be a monic polynomial such that \( f(x) = 0 \). The minimum polynomial \( f_{\text{min}}^x(T) \) divides \( f(T) \) in \( \mathbb{Q}[T] \). Since the minimum polynomial of \( x \) is monic, we have that \( f(T) = g(T)f_{\text{min}}^x(T) \) with \( g(T) \in \mathbb{Q}[T] \) monic. By Gauß’s Lemma we have that both \( f_{\text{min}}^x(T) \) and \( g(T) \) are in \( \mathbb{Z}[T] \), as required.

(ii) \( \Rightarrow \) (iii) This is immediate from Prop. 3.2(ii).

(iii) \( \Rightarrow \) (iv) Let \( n \) be the degree of \( f_{\text{char}}(T) = \sum_i a_i T^i \). Let \( M \) be the additive group generated by \( 1, x, x^2, \ldots, x^{n-1} \). The finitely generated group \( M \) satisfies \( xM \subset M \) because \( x \cdot x^{n-1} = x^n = -a_{n-1}x^{n-1} - \cdots - a_1x - a_0 \in M \).

(iv) \( \Rightarrow \) (i) Let \( M \neq 0 \) be generated by \( e_1, e_2, \ldots, e_m \in F \). Since \( xM \subset M \) there exist \( a_{ij} \in \mathbb{Z} \) such that

\[
xe_i = \sum_{j=1}^{m} a_{ij} e_j \quad \text{for all } 1 \leq i \leq m,
\]

in other words

\[
\begin{pmatrix}
a_{11} & a_{12} & \cdots & a_{1m} \\
a_{21} & a_{22} & \cdots & a_{2m} \\
\vdots & \vdots & \ddots & \vdots \\
a_{m1} & a_{m2} & \cdots & a_{mm}
\end{pmatrix}
= \begin{pmatrix}
e_1 \\
e_2 \\
\vdots \\
e_m
\end{pmatrix}
= x \begin{pmatrix}
e_1 \\
e_2 \\
\vdots \\
e_m
\end{pmatrix}.
\]

Since \( M \neq 0 \), at least one of the \( e_i \) is not zero. This implies that

\[
\det((a_{ij}) - x \cdot \text{Id}) = 0
\]

and that the monic polynomial

\[
f(T) = \det(T \cdot \text{Id} - (a_{ij})) \in \mathbb{Z}[T]
\]

vanishes in \( x \). This proves the lemma. \( \square \)
Proposition 4.3. The set $O_F$ of integral elements of a number field $F$ is a subring of $F$.

Proof. It is easy to see that it suffices to show that $x + y$ and $xy$ are integral whenever $x$ and $y$ are integral. Let therefore $x, y \in F$ be integral. By Lemma 4.2 there exist non-trivial finitely generated subgroups $M_1$ and $M_2$ of $F$, such that $xM_1 \subset M_1$ and $yM_2 \subset M_2$. Let $e_1, e_2, \ldots, e_l$ be generators of $M_1$ and let $f_1, f_2, \ldots, f_m$ be generators of $M_2$. Let $M_3$ be the additive subgroup of $F$ generated by the products $e_if_j$ for $1 \leq i \leq l$ and $1 \leq j \leq m$. It is easy to see that $(x + y)M_3 \subset M_3$ and that $xyM_3 \subset M_3$. \hfill \Box

In Chapter 5 we will encounter a more general notion of “integrality”: if $R \subset S$ is an extension of commutative rings, then $x \in S$ is said to be integral over $R$, if there exists a monic polynomial $f(T) \in R[T]$ such that $f(x) = 0$. Integers of rings of number fields are, in this sense, integral over $\mathbb{Z}$.

In general, it is a difficult problem to determine the ring of integers of a given number field. According to Thm. 2.2, every number field $F$ can be written as $F = \mathbb{Q}(\alpha)$ for some $\alpha \in F$. A similar statement for rings of integers is, in general, false: there exist number fields $F$ such that $O_F \neq \mathbb{Z}[\alpha]$ for any $\alpha \in O_F$. For example, the field $\mathbb{Q}(\sqrt{20})$ has $\mathbb{Z}[\sqrt{20}, \sqrt{50}]$ as a ring of integers and this ring is not of the form $\mathbb{Z}[\alpha]$ for any $\alpha$ (see Exercise 9.E). There do, in fact, exist many number fields $F$ for which $O_F$ is not of the form $\mathbb{Z}[\alpha]$ for any $\alpha$. For instance, it was recently shown by M.-N. Gras [21], that “most” subfields of the cyclotomic fields have this property.

Number fields of degree 2 are called quadratic number fields. It is relatively easy to do computations in these fields. The rings of integers of quadratic fields happen to be generated by one element only:

Example 4.4. Let $F$ be a quadratic number field. Then

(i) There exists a unique squarefree integer $d \in \mathbb{Z}$ such that $F = \mathbb{Q}(\sqrt{d})$.

(ii) Let $d$ be a squarefree integer. The ring of integers $O_F$ of $F = \mathbb{Q}(\sqrt{d})$ is given by

$$O_F = \mathbb{Z}[\sqrt{d}] \quad \text{if } d \equiv 2 \text{ or } 3 \pmod{4},$$

$$= \mathbb{Z}\left\{\frac{1 + \sqrt{d}}{2}\right\} \quad \text{if } d \equiv 1 \pmod{4}.$$

Proof. (i) For any $\alpha \in F \setminus \mathbb{Q}$ one has that $F = \mathbb{Q}(\alpha)$. The number $\alpha$ is a zero of an irreducible polynomial $f(T) \in \mathbb{Q}[T]$ of degree 2 and, it is easy to see that $F = \mathbb{Q}(\sqrt{d})$ where $d \in \mathbb{Q}$ is the discriminant of $f$. The field $\mathbb{Q}(\sqrt{d})$ does not change if we divide or multiply $d$ by squares of non-zero integers. We conclude that $F = \mathbb{Q}(\sqrt{d})$ for some squarefree integer $d$. The uniqueness of $d$ will be proved after the proof of part (ii).

(ii) Let $\alpha \in F = \mathbb{Q}(\sqrt{d})$. Then $\alpha$ can be written as $\alpha = a + b\sqrt{d}$ with $a, b \in \mathbb{Q}$. The characteristic polynomial is given by

$$f_{\text{char}}(T) = T^2 - 2aT + (a^2 - db^2).$$

Therefore, a necessary and sufficient condition for $\alpha = a + b\sqrt{d}$ to be in $O_F$, is that $2a \in \mathbb{Z}$ and $a^2 - db^2 \in \mathbb{Z}$.

It follows that either $a \in \mathbb{Z}$ or $a \in \frac{1}{2} + \mathbb{Z}$. We write $b = u/v$ with $u, v \in \mathbb{Z}, v \neq 0$ and $\gcd(u, v) = 1$. If $a \in \mathbb{Z}$, then $v^2d \in \mathbb{Z}$, and we see that $v^2$ divides $u^2d$. Since $\gcd(u, v) = 1$, we conclude that $v^2$ divides $d$. Since $d$ is squarefree, this implies that $v^2 = 1$ and that $b \in \mathbb{Z}$. If $a \in \frac{1}{2} + \mathbb{Z}$, then $4du^2/v^2 \in \mathbb{Z}$. Since $\gcd(u, v) = 1$ and $d$ is squarefree this implies that $v^2$ divides 4. Since $a \in \frac{1}{2} + \mathbb{Z}$, we have that $b \notin \mathbb{Z}$ and $v^2 \neq 1$. Therefore $v^2 = 4$ and $b \in \frac{1}{2} + \mathbb{Z}$. Now we have
that $a, b \in \frac{1}{2} + Z$, and this together with the fact that $a^2 - db^2 \in Z$ is easily seen to imply that $(d - 1)/4 \in Z$.

We conclude that for $d \equiv 1 \pmod{4}$ one has that $O_F = \{a + b\sqrt{d} \mid a, b \in Z \text{ or } a, b \in \frac{1}{2} + Z\}$. Equivalently, $O_F = Z[\frac{1 + \sqrt{d}}{2}]$. In the other cases one has that $O_F = Z[\sqrt{d}]$.

(i) It remains to finish the proof of (i). Suppose $F = \mathbb{Q}(\sqrt{d})$ for some squarefree integer $d$. The set
\[ \{N(x) \mid x \in O_F \text{ with } \text{Tr}(x) = 0\} \]
is equal to $\{a^2 d \mid a \in Z\}$. This shows that $d$ is determined by $O_F$ and hence by $F$. \qed

Next we discuss discriminants of integral elements $\omega_1, \ldots, \omega_n \in F$.

**Proposition 4.5.** Let $F$ be a number field of degree $n$.

(i) If $\omega_1, \ldots, \omega_n \in O_F$ then $\Delta(\omega_1, \ldots, \omega_n) \in Z$.

(ii) Elements $\omega_1, \ldots, \omega_n \in O_F$ generate $O_F$ as an abelian group if and only if $0 \neq \Delta(\omega_1, \ldots, \omega_n) \in Z$ has minimal absolute value.

(iii) There exist $\omega_1, \ldots, \omega_n \in O_F$ that generate $O_F$. For any such a set of $n$ generators one has that $O_F = Z\omega_1 + \cdots + Z\omega_n \cong Z^n$. The value of $\Delta(\omega_1, \ldots, \omega_n)$ is independent of the basis and only depends on the ring $O_F$.

**Proof.** (i) Clear, because $\omega_i \omega_j \in O_F$ for all $i$ and $j$; hence $\text{Tr}(\omega_i \omega_j) \in Z$.

(ii) Suppose $\omega_1, \ldots, \omega_n$ generate $O_F$ as an abelian group. It follows from Exercise (4.A) that $\omega_1, \ldots, \omega_n$ is then in particular a $\mathbb{Q}$-basis of $F$, so $\Delta(\omega_1, \ldots, \omega_n) \neq 0$ by Prop. 3.4(ii). If $\omega'_1, \ldots, \omega'_n$ is any set of $n$ elements in $O_F$ then there exist $\lambda_{ij} \in Z$ such that $\omega'_i = \sum_{j=1}^n \lambda_{ij} \omega_j$. By Prop. 3.4(iii) we have $\Delta(\omega'_1, \ldots, \omega'_n) = \det(\lambda_{ij})^2 \cdot \Delta(\omega_1, \ldots, \omega_n)$. Since $\det(\lambda_{ij})^2$ is a positive integer, it follows that the discriminant $\Delta(\omega_1, \ldots, \omega_n)$ has minimal absolute value.

Conversely, suppose $0 \neq \Delta(\omega_1, \ldots, \omega_n)$ is minimal. If $\omega_1, \ldots, \omega_n$ do not generate $O_F$ as an abelian group, there exists an element $x = \sum_i \lambda_i \omega_i \in O_F$ which is not in the group generated by the $\omega_i$. This means there is an index $j$ such that $\lambda_j \notin Z$. Possibly after replacing $x$ by $x + m\omega_j$ for some $m \in Z$, we may further assume that $0 < \lambda_j < 1$. Now let $\omega'_i := \omega_i$ for $i \neq j$ and $\omega'_j := x$. Using Prop. 3.4(iii) one readily sees that $|\Delta(\omega'_1, \ldots, \omega'_n)| = \lambda_j^2 \cdot |\Delta(\omega_1, \ldots, \omega_n)|$. Hence $|\Delta(\omega'_1, \ldots, \omega'_n)|$ is integral (by (i)), non-zero, but strictly smaller than $|\Delta(\omega_1, \ldots, \omega_n)|$. This contradicts our assumptions; hence $\omega_1, \ldots, \omega_n$ generate $O_F$.

(iii) Take any set $\{\omega_1, \ldots, \omega_n\} \subset O_F$ for which $0 \neq \Delta(\omega_1, \ldots, \omega_n)$ is minimal. By (ii), this last assumption is equivalent to saying that the $\omega_i$ generate $O_F$. In other words: the natural map $\gamma: \mathbb{Z}^n \rightarrow O_F$ given by $(m_1, \ldots, m_n) \mapsto m_1 \omega_1 + \cdots + m_n \omega_n$ is surjective. On the other hand, by Prop. 3.4(ii) $\{\omega_1, \ldots, \omega_n\}$ is a $\mathbb{Q}$-basis for $F$, so $\gamma$ is also injective. Hence $O_F = \oplus_{i=1}^n Z\omega_i$.

Any other choice $\omega'_1, \ldots, \omega'_n$ of an integral basis is related to the first choice by $\omega'_i = \sum_{j=1}^n \lambda_{ij} \omega_j$, where $A = (\lambda_{ij})$ is a matrix in $\text{GL}_n(Z)$. But then $\det(A) = \pm 1$ (Exercise (4.M)), so by Prop. 3.4(iii) we have $\Delta(\omega'_1, \ldots, \omega'_n) = \Delta(\omega_1, \ldots, \omega_n)$. \qed

A set of $n$ elements $\omega_1, \ldots, \omega_n \in O_F$ such that $O_F = Z\omega_1 + \cdots + Z\omega_n$ (as additive groups) is referred to as an integral basis for $O_F$.

**Corollary 4.6.** Let $F$ be a number field with ring of integers $O_F$. Then

(i) Every ideal $I \neq 0$ of $O_F$ has finite index $|O_F : I|$.

(ii) Every ideal $I$ of $O_F$ is a finitely generated abelian group.
(iii) Every prime ideal \( p \neq 0 \) of \( O_F \) is maximal.

**Proof.** Let \( I \neq 0 \) be an ideal of \( O_F \). By Exercise 4.D, the ideal \( I \) contains an integer \( m \in \mathbb{Z}_{>0} \). Therefore \( mO_F \subset I \). By Prop. 4.5(iii), the additive group of \( O_F \) is isomorphic to \( \mathbb{Z}^n \), where \( n \) is the degree of \( F \). It follows that \( O_F/I \), being a quotient of \( O_F/mO_F \cong \mathbb{Z}^n/m\mathbb{Z}^n \) is finite.

(ii) Let \( I \) be an ideal of \( O_F \). Since the statement is trivial when \( I = 0 \), we will assume that \( I \neq 0 \) and choose an integer \( m \in \mathbb{Z}_{>0} \) in \( I \). By (i) the ring \( O_F/mO_F \) is finite and therefore the ideal \( I \) (mod \( mO_F \)) can be generated, as an abelian group, by finitely many elements, say, \( \alpha_1, \ldots, \alpha_k \). It easily follows that the ideal \( I \) is then generated by \( \alpha_1, \ldots, \alpha_k \) and \( m\omega_1, \ldots, m\omega_n \), where the \( \omega_i \) are a \( \mathbb{Z} \)-basis for the ring of integers \( O_F \).

(iii) Let \( p \neq 0 \) be a prime ideal of \( O_F \). By (i) the ring \( O_F/p \) is a finite domain. Since finite domains are fields, it follows that \( p \) is a maximal ideal. \( \square \)

As a consequence of Cor. 4.6, the following definition is now justified:

**Definition.** Let \( F \) be a number field and let \( I \neq 0 \) be an ideal of the ring of integers \( O_F \) of \( F \). We define the norm \( N(I) \) of the ideal \( I \) by

\[
\]

Another application of Prop. 4.5 is the following. Let \( F \) be a number field of degree \( n \) and let \( \omega_1, \ldots, \omega_n \in F \). By Prop. 3.4(iii) the discriminant \( \Delta(\omega_1, \omega_2, \ldots, \omega_n) \) does not depend on \( \omega_1, \ldots, \omega_n \), but merely on the additive group these numbers generate. This justifies the following definition.

**Definition.** Let \( F \) be a number field of degree \( n \). The discriminant of \( F \) is the discriminant \( \Delta(\omega_1, \omega_2, \ldots, \omega_n) \) of an integral basis \( \omega_1, \omega_2, \ldots, \omega_n \) of \( O_F \).

Since \( 1 \) is a \( \mathbb{Z} \)-basis for \( \mathbb{Z} \), we see that the discriminant of \( \mathbb{Q} \) is \( 1 \). As an example we calculate the discriminant of a quadratic field.

**Example 4.7.** Let \( F \) be a quadratic field. By Example 4.4 there exists a unique squarefree integer \( d \) such that \( F = \mathbb{Q}(\sqrt{d}) \). If \( d \equiv 2 \) or \( 3 \pmod{4} \), the ring of integers of \( F \) is \( \mathbb{Z}[\sqrt{d}] \). We take \( \{1, \sqrt{d}\} \) as a \( \mathbb{Z} \)-basis of \( O_F \). Then

\[
\Delta_{\mathbb{Q}(\sqrt{d})} = \det \begin{pmatrix} \text{Tr}(1 \cdot 1) & \text{Tr}(1 \cdot \sqrt{d}) \\ \text{Tr}(1 \cdot \sqrt{d}) & \text{Tr}(\sqrt{d} \cdot \sqrt{d}) \end{pmatrix} = \det \begin{pmatrix} 2 & 0 \\ 0 & 2d \end{pmatrix} = 4d.
\]

If \( d \equiv 1 \pmod{4} \), the ring of integers of \( F \) is \( \mathbb{Z}[\frac{1+\sqrt{d}}{2}] \). We take \( \{1, \frac{1+\sqrt{d}}{2}\} \) as a \( \mathbb{Z} \)-basis of \( O_F \). Then

\[
\Delta_{\mathbb{Q}(\sqrt{d})} = \det \begin{pmatrix} \text{Tr}(1 \cdot 1) & \text{Tr}(1 \cdot \frac{1+\sqrt{d}}{2}) \\ \text{Tr}(1 \cdot \frac{1+\sqrt{d}}{2}) & \text{Tr}(\frac{1+\sqrt{d}}{2} \cdot \frac{1+\sqrt{d}}{2}) \end{pmatrix} = \det \begin{pmatrix} 2 & 1 \\ 1 & \frac{d+1}{2} \end{pmatrix} = d.
\]

For \( d = -1 \) we find that the ring of integers of \( \mathbb{Q}(i) \) is the well known ring \( \mathbb{Z}[i] \) of Gaussian integers.

For \( d = -3 \) we find the ring \( \mathbb{Z}[\{1+\sqrt{-3}/2\}] \) of Eisenstein integers. The latter ring is isomorphic to the ring \( \mathbb{Z}[\zeta_3] \) where \( \zeta_3 \) denotes a primitive root of unity.

In general, it is rather difficult to calculate the discriminant and the ring of integers of a number field. We will come back to this problem in Chapter 9. The following proposition often comes in handy.
Proposition 4.8. Let $F$ be a number field of degree $n$.

(i) Suppose $\omega_1, \omega_2, \ldots, \omega_n \in O_F$ have the property that $\Delta(\omega_1, \omega_2, \ldots, \omega_n)$ is a squarefree integer. Then $O_F = \sum_i \omega_i \mathbb{Z}$.

(ii) If there exists $\alpha \in O_F$ such that the discriminant of $f_{\min}^\alpha(T)$ is squarefree, then $O_F = \mathbb{Z}[\alpha]$ and $\Delta_F = \Delta(1, \alpha, \ldots, \alpha^{n-1}) = \text{Disc}(f_{\min}^\alpha)$.

Proof. (i) It follows from Prop. 3.4(iii) that $\Delta(\omega_1, \omega_2, \ldots, \omega_n) = \det(M)^2 \cdot \Delta_F$, where $M \in \text{GL}_2(\mathbb{Z})$ is the matrix expressing the $\omega_i$ in terms of a $\mathbb{Z}$-base of $O_F$. Since $\det(M)^2$ is the square of an integer, part (i) follows.

(ii) If we take $\{\omega_1, \ldots, \omega_n\} = \{1, \alpha, \alpha^2, \ldots, \alpha^{n-1}\}$, the result in (ii) follows from (i) and the fact, proved in Prop. 3.5, that $\Delta(1, \alpha, \ldots, \alpha^{n-1}) = \text{Disc}(f_{\min}^\alpha)$.

Example. Let $\alpha$ be a zero of the polynomial $f(T) = T^3 - T - 1 \in \mathbb{Z}[T]$. Since $f(T)$ is irreducible modulo 2, it is irreducible over $\mathbb{Q}$. Put $F = \mathbb{Q}(\alpha)$. By Prop. 3.2(ii) the characteristic polynomial of $\alpha$ is also equal to $f(T)$. In order to calculate the discriminant of $f$, one can employ various methods. See Exercise 3.K for an efficient algorithm involving resultants of polynomials. Here we just use the definition of the discriminant. Let us calculate

$$\Delta(1, \alpha, \alpha^2) = \begin{pmatrix} \text{Tr}(1) & \text{Tr}(\alpha) & \text{Tr}(\alpha^2) \\ \text{Tr}(\alpha) & \text{Tr}(\alpha^2) & \text{Tr}(\alpha^3) \\ \text{Tr}(\alpha^2) & \text{Tr}(\alpha^3) & \text{Tr}(\alpha^4) \end{pmatrix}.$$ 

The trace of 1 is 3. The trace of $\alpha$ is equal to $-1$ times the coefficient at $T^2$ of $F(T)$ and hence is 0. In general, the traces $\text{Tr}(\alpha^k)$ are equal to the power sums $p_k = \varphi_1(\alpha)^k + \varphi_2(\alpha)^k + \varphi_3(\alpha)^k$ for $k \geq 0$. Newton’s formulas (see Exercise 3.I) relate these sums to the coefficients $s_k$ of the minimum polynomial of $\alpha$.

In the notation of Exercise 3.I we have that $\text{Tr}(\alpha^2) = p_2 = -2s_2 + p_1s_1 = -2 \cdot (-1) + 0 = 2$. We obtain the other values of $\text{Tr}(\alpha^k)$ by using the additivity of the trace: since $\alpha^3 = \alpha + 1$, we have $\text{Tr}(\alpha^3) = \text{Tr}(\alpha + 1) = 0 + 3 = 3$ and $\text{Tr}(\alpha^4) = \text{Tr}(\alpha^2 + \alpha) = 2 + 0 = 2$. Therefore

$$\Delta(1, \alpha, \alpha^2) = \begin{pmatrix} 3 & 0 & 2 \\ 0 & 2 & 3 \\ 2 & 3 & 2 \end{pmatrix} = -23.$$ 

By Prop. 4.8 we can now conclude that the ring of integers of $\mathbb{Q}(\alpha)$ is $\mathbb{Z}[\alpha]$ and that the discriminant $\Delta_{\mathbb{Q}(\alpha)}$ is equal to $-23$.

Exercises

(4.A) Let $F$ be a number field and let $\alpha \in F$. Show that there exist an integer $0 \neq m \in \mathbb{Z}$ such that $m \alpha \in O_F$.

(4.B) Show that for every number field $F$ there exists an integral element $\alpha \in O_F$ such that $F = \mathbb{Q}(\alpha)$.

(4.C) Let $F$ be a number field. Show that the field of fractions of $O_F$ is $F$.

(4.D) Let $F$ be a number field. Show that every ideal $I \neq 0$ of $O_F$ contains a non-zero integer $m \in \mathbb{Z}$.

(4.E) Let $F$ be a number field and let $\alpha \in O_F$. Show that $N(\alpha) = \pm 1$ if and only if $\alpha$ is a unit of the ring $O_F$.

(4.F) Let $F \subset K$ be an extension of number fields. Show that $O_K \cap F = O_F$.

(4.G) Let $F$ be a number field. Let $r_1$ be the number of distinct embeddings $F \hookrightarrow \mathbb{R}$ and let $2r_2$ be the number of remaining homomorphisms $F \hookrightarrow \mathbb{C}$. Show that the sign of $\Delta_F$ is $(-1)^{r_2}$.
(4.H) Determine the ring of integers and the discriminant of the number field \( \mathbb{Q}(\alpha) \) where \( \alpha \) satisfies \( \alpha^3 + \alpha - 1 = 0 \).

(4.I) Let \( F \) and \( K \) be two quadratic number fields. Show that if \( \Delta_F = \Delta_K \), then \( F \cong K \).

(4.J) Let \( d \) be a negative squarefree integer. Determine the unit group of the ring of integers of the field \( \mathbb{Q}(\sqrt{d}) \).

(4.K) Let \( R \) be a commutative ring. An \( R \)-algebra \( A \) is a ring together with a ring homomorphism \( R \to A \). Alternatively, \( A \) is a ring provided with a multiplication \( R \times A \to A \) by elements of \( R \) that satisfies

\[
\begin{align*}
\lambda(x + y) &= \lambda x + \lambda y, \\
(\lambda + \mu)x &= \lambda x + \mu x, \\
(\lambda\mu)x &= \lambda(\mu x), \\
1x &= x,
\end{align*}
\]

for \( \lambda, \mu \in R \) and \( x, y \in A \).

(i) Show that the two definitions of an \( R \)-algebra are equivalent.

(ii) If \( R = K \) is a field, show that a \( K \)-algebra is, in particular, a vector space over \( K \).

(iii) Show that every ring has a natural structure of a \( \mathbb{Z} \)-algebra.

(4.L) Let \( K \) be a field.

(i) Let \( A \) be a finite dimensional \( K \)-algebra (see Exercise 4.K). Show: \( A \) is a domain if and only if it is a field.

(ii) Show that every prime ideal \( \mathfrak{p} \neq 0 \) of \( K[X] \) is also maximal.

(4.M) Let \( M \in \text{GL}_n(\mathbb{Z}) \) be an invertible matrix. Show that \( \det(M) = \pm 1 \).

(4.N) Let \( n \geq 1 \) be an integer and let \( \zeta_n \) denote a primitive \( n \)-th root of unity. Show that \( \zeta_n - 1 \) is a unit of the ring of integers of \( \mathbb{Q}[\zeta_n] \) if and only if \( n \) is not the power of a prime. (Hints: (a) substitute \( T = 1 \) (!) in \( (T^n - 1)/(T - 1) = \prod_{d|n, d \neq 1} \Phi_d(T) \); (b) use that \( \Phi_d(1) = p \) if \( d > 1 \) is a power of a prime number \( p \), see exercise (2.K)(v); (c) use exercises (3.B) and (4.E).)

*(4.O) (Stickelberger, 1923) Let \( F \) be a number field of degree \( n \). Let \( \{\omega_1, \omega_2, \ldots, \omega_n\} \) be a \( \mathbb{Z} \)-basis for the ring of integers of \( F \). Let \( \varphi_i: F \to \mathbb{C} \) be the embeddings of \( F \) into \( \mathbb{C} \). By \( S_n \) we denote the symmetric group on \( n \) symbols and by \( A_n \) the normal subgroup of even permutations. We define

\[
\Delta^+ = \sum_{\tau \in A_n} \prod_{i=1}^n \varphi_i(\omega_{\tau(i)}) \quad \text{and} \quad \Delta^- = \sum_{\tau \in S_n \setminus A_n} \prod_{i=1}^n \varphi_i(\omega_{\tau(i)}).
\]

Prove, using Galois theory, that \( \Delta^+ + \Delta^- \) and \( \Delta^+ \Delta^- \) are in \( \mathbb{Z} \). Conclude that \( \Delta_F = (\Delta^+ + \Delta^-)^2 - 4\Delta^+ \Delta^- \) is 0 or 1 modulo 4.
Appendix to chapter 4: Computing the ring of integers and the discriminant.

The purpose of this appendix is to explain how—at least in principle—one can determine the ring of integers of a number field, and its discriminant. Throughout, we consider a number field $F$ of degree $n$. In the algorithm we consider a $\mathbb{Q}$-basis $\beta_1, \ldots, \beta_n$ for $F$ with $\beta_i \in O_F$ for all $i$, and such that $\Delta(\beta_1, \ldots, \beta_n)$ is known. There is an initialization step to bring us into such a situation. Once we have the $\beta_i$, we decide whether or not they form an integral basis; if not then we find new elements $\beta_1', \ldots, \beta_n'$ that are closer to being an integral basis, and with these new elements we repeat the procedure.

The procedure we describe here is not one that would actually be used by computer packages. With more techniques one can give faster algorithms. But with the relatively simple techniques that we have at our disposal at this stage, we arrive at a procedure that works well enough to be of interest.

Initialization. We assume given a number field $F$ of degree $n$, in the form $F = \mathbb{Q}(\alpha_1, \ldots, \alpha_r)$.

Step A: Find a primitive element $\alpha$ in $F$ using the method as in the proof of Thm. 22.

Step B: Find a primitive element $\alpha$ in $O_F$; cf. Exercise (4.B). (If the primitive element $\alpha$ from Step A is not in $O_F$, replace $\alpha$ by $m \alpha$ for a suitably chosen integer $m$.)

After completing Step B, let $f = f_{\min}^\alpha$ be the minimum polynomial of $\alpha$ and set $\beta_i := \alpha^{i-1}$ for $i = 1, \ldots, n$. Compute the discriminant $\Delta(\beta_1, \ldots, \beta_n) = \Delta(1, \alpha, \ldots, \alpha^{n-1})$ by one of the formulas given in Prop. 3.5.

Main procedure. We assume given a $\mathbb{Q}$-basis $\beta_1, \ldots, \beta_n$ for $F$ with $\beta_i \in O_F$ for all $i$. We further assume that $\Delta(\beta_1, \ldots, \beta_n)$ is known.

Step 1: Test whether $\Delta(\beta_1, \ldots, \beta_n)$ is squarefree. If it is squarefree then $\beta_1, \ldots, \beta_n$ is an integral basis, $\Delta_F = \Delta(\beta_1, \ldots, \beta_n)$, and the procedure stops. If $\Delta(\beta_1, \ldots, \beta_n)$ is not squarefree, go to Step 2.

Step 2: Let $p$ run over all prime numbers such that $p^2$ divides $\Delta(\beta_1, \ldots, \beta_n)$. For each such $p$, let $y$ run over all elements of the form

$$y = m_1 \beta_1 + \cdots + m_n \beta_n$$

with $m_i \in \{0, 1, \ldots, p-1\}$ for all $i$ and $(m_1, \ldots, m_n) \neq (0, \ldots, 0)$. Test if $y/p$ is integral. If you find an element $y$ such that $y/p$ is integral, go to Step 3. If you do not find any $p$ and any element $y$ such that $y/p$ is integral then $\beta_1, \ldots, \beta_n$ is an integral basis, $\Delta_F = \Delta(\beta_1, \ldots, \beta_n)$, and the procedure stops.

Step 3: The previous step has produced a prime number $p$ such that $p^2$ divides $\Delta(\beta_1, \ldots, \beta_n)$ and integers $m_1, \ldots, m_n \in \{0, 1, \ldots, p-1\}$, not all zero, such that $y/p$ is integral, where $y = m_1 \beta_1 + \cdots + m_n \beta_n$. We are going to modify $y$ such that $m_j = 1$ for some $j$. If there is already an index $j$ with $m_j = 1$, go to Step 4. If not, choose an index $j$ such that $m_j \neq 0$. Take an integer $r$ such that $rm_j \equiv 1 \mod p$. For $i = 1, \ldots, n$, let $\mu_i \in \{0, 1, \ldots, p-1\}$ be the unique element that is congruent to $rm_i$ modulo $p$. Note that, by construction, $\mu_j = 1$. Now replace $y$ by $\mu_1 \beta_1 + \cdots + \mu_n \beta_n$.

Step 4: After the previous step we can choose an index $j$ with $m_j = 1$. Now set

$$\beta'_i := \begin{cases} \beta_i & \text{if } i \neq j; \\ y/p & \text{if } i = j. \end{cases}$$

26
By construction the elements $\beta_1', \ldots, \beta_n'$ are again in $O_F$, and Prop. 3.4(iii) gives that

$$\Delta(\beta_1', \ldots, \beta_n') = (1/p^2) \cdot \Delta(\beta_1, \ldots, \beta_n).$$

Now repeat the procedure with $\beta_1', \ldots, \beta_n'$.

**Remark.** In practice one can usually considerably speed up the procedure. For instance, suppose we start with an integral primitive element $\alpha$. Suppose we have a prime $p$ with $p^2$ dividing $\Delta(1, \alpha, \ldots, \alpha^{n-1})$, and an element $y = m_1 + m_2 \alpha + \cdots + m_n \alpha^{n-1}$ with $m_i \in \{0, \ldots, p-1\}$ such that $y/p$ is integral. Then it is tempting to see what happens if we replace $1, \alpha, \ldots, \alpha^{n-1}$ by $1, \alpha', \ldots, (\alpha')^{n-1}$, where $\alpha' = y/p$, rather than replacing one base vector at a time. This may give a shortcut, though success is not guaranteed.

Also we may use a different initialization than the one described above. This applies if we already know (or see) some basis $\beta_1, \ldots, \beta_n$ that is not necessarily of the form $1, \alpha, \ldots, \alpha^{n-1}$ but for which we can compute the discriminant.

**Correctness of the algorithm.** It is clear that the algorithm breaks off after finitely many steps, because each time we go through the procedure, either the algorithm stops or we arrive at a new basis $\beta_1', \ldots, \beta_n'$ for which $\Delta(\beta_1', \ldots, \beta_n')$ is strictly smaller in absolute value than it was in the previous round.

All that remains to be shown is the following. If $\beta_1, \ldots, \beta_n$ is a $\mathbb{Q}$-basis of $F$ with $\beta_i \in O_F$ for all $i$, and if $\mathbb{Z}\beta_1 + \cdots + \mathbb{Z}\beta_n$ is not the full ring of integers $O_F$, then there exist:

(a) a prime number $p$ with $p^2 \mid \Delta(\beta_1, \ldots, \beta_n)$,

(b) integers $m_i \in \{0, 1, \ldots, p-1\}$, not all zero, such that

(c) $(m_1 \beta_1 + \cdots + m_n \beta_n)/p$ is integral.

To prove this, we use one result from group theory. A proof shall be given in Cor. 7.3. The result we need is as follows. Consider an $n \times n$ matrix $A$ with coefficients in $\mathbb{Z}$. Consider the abelian group $M := \mathbb{Z}^n$, and let $L := A(M) \subset M$ be the image of the linear map $M \to M$ described by the matrix $A$. Then $[M : L] < \infty$ if and only if $\det(A) \neq 0$, and if this holds then we have $[M : L] = |\det(A)|$.

We choose an integral basis $\omega_1, \ldots, \omega_n$ for $O_F$. Let $A = (a_{ij})$ be the $n \times n$ matrix such that $\beta_j = \sum_{i=1}^n a_{ij} \omega_i$ for all $j$. By Prop. 3.4(iii) we have

$$\Delta(\beta_1, \ldots, \beta_n) = \det(A)^2 \cdot \Delta_F.$$

But $\Delta(\beta_1, \ldots, \beta_n) \neq 0$, because $\beta_1, \ldots, \beta_n$ is a $\mathbb{Q}$-basis for $F$; so we have $\det(A) \neq 0$. The fact stated above then tells us that $L := \mathbb{Z}\beta_1 + \cdots + \mathbb{Z}\beta_n$ has finite index equal to $|\det(A)|$ in $O_F$.

Now we have assumed that $\beta_1, \ldots, \beta_n$ is not yet an integral basis, so $|\det(A)| > 1$. Let $p$ be any prime number that divides $\det(A)$. Note that condition (a) holds for this prime. Further, $p$ divides the order of the finite group $O_F/L$. By Cauchy’s theorem this group therefore has an element of order $p$. If $\eta \in O_F/L$ is such an element, then for any representative $\tilde{\eta} \in O_F$ of the class $\eta$ we have that $\tilde{\eta} \notin L$ but $p\tilde{\eta} \in L$. Therefore we can write $\tilde{\eta} = (m_1' \beta_1 + \cdots + m_n' \beta_n)/p$ for some integers $m_i'$ that are not all $\equiv 0 \mod p$. Let $m_i$ be the unique integer in $\{0, 1, \ldots, p-1\}$ with $m_i \equiv m_i' \mod p$; note that the $m_i$ are not all zero, so (b) holds. Finally, if $y = m_1 \beta_1 + \cdots + m_n \beta_n$ then $y/p \in \tilde{\eta} + L \subset O_F$, so (c) holds.

A final word about Step 3 of the procedure. There we go from an element $y$ to an element $y'$, and by construction there is an $r \in \mathbb{Z}$ with $p \nmid r$ such that $y' = ry + p \cdot L$. But then it is clear that
in fact \( y' + p \cdot L = ry + p \cdot L \), so the classes of \( y/p \) and \( y'/p \) span the same subgroup of \( O_F/L \). In particular, \( L' := \mathbb{Z}\beta_1 + \cdots + \mathbb{Z}\beta_n \) contains \( L \) with \( [L' : L] = p \), and \( \Delta(\beta_1, \ldots, \beta_n) = \Delta(\beta_1, \ldots, \beta_n)/p^2 \).

This proves the correctness of the algorithm.

**Example.** Let \( f := T^3 - 3T^2 + 7T - 45 \) and define \( F := \mathbb{Q}[T]/(f) \). Write \( \beta \in F \) for the class of \( T \) modulo \( (f) \). Note that \( f \) is irreducible in \( \mathbb{Q}[T] \) because it is irreducible modulo 11, so that \( [F : \mathbb{Q}] = 3 \) and \( \beta \) is a primitive element.

Prop. 3.5 gives that \( \Delta(1, \beta, \beta^2) = \text{Disc}(f) = -N(3\beta^2 - 6\beta + 7) \). Write \( \xi := 3\beta^2 - 6\beta + 7 \), and compute the matrix of “multiplication by \( \xi \)” with respect to the basis \( \{1, \beta, \beta^2\} \). E.g., to get the second column we write

\[
\xi \cdot \beta = 3\beta^3 - 6\beta^2 + 7\beta = 9\beta^2 - 21\beta + 135 - 6\beta^2 + 7\beta = 3\beta^2 - 14\beta + 135,
\]

so the coefficients in the second column are 135, -14 and 3. As a result we find that

\[
\text{Disc}(f) = - \det \begin{pmatrix} 7 & 135 & 135 \\ -6 & -14 & 114 \\ 3 & 3 & -5 \end{pmatrix} = - \det \begin{pmatrix} 7 & 135 & 0 \\ -6 & -14 & 128 \\ 3 & 3 & -8 \end{pmatrix}
\]

and after a little calculation we find that \( \text{Disc}(f) = -43456 = -2^6 \cdot 7 \cdot 97 \).

Hence the only prime number \( p \) with \( p^2 | \text{Disc}(f) \) is \( p = 2 \). So we start looking for linear combinations \( y = a_0 + a_1\beta + a_2\beta^2 \) such that \( y/2 \) is integral; here \( a_i \in \{0, 1\} \) and \( (a_0, a_1, a_2) \neq (0, 0, 0) \). Let us try \( y = 1 + \beta \). We compute:

\[
(1 + \beta)^2 = 1 + 2\beta + \beta^2 \\
(1 + \beta)^3 = 1 + 3\beta + 3\beta^2 + \beta^3 = 46 - 4\beta + 6\beta^2
\]

and with this we readily find that \( 1 + \beta \) has minimum polynomial \( T^3 - 6T^2 + 16T - 56 \). Hence \( \beta' := (1 + \beta)/2 \) has minimum polynomial \( T^3 - 3T^2 + 4T - 7 \) and is therefore an integral element which is not in \( \mathbb{Z} + \mathbb{Z}\beta + \mathbb{Z}\beta^2 \).

As our new basis we try \( \{1, \beta', (\beta')^2\} \). We have

\[
\begin{pmatrix} 1 \\ \beta' \\ (\beta')^2 \end{pmatrix} = \begin{pmatrix} 1/4 & 1/4 & 0 \\ 1/4 & 1/4 & 1/4 \\ 1/12 & 1/12 & 1/12 \end{pmatrix} \begin{pmatrix} 1 \\ \beta \\ \beta^2 \end{pmatrix}
\]

and Prop. 3.4(iii) combined with Prop. 3.5 gives that

\[
\Delta(1, \beta, (\beta')^2) = (1/8)^2 \cdot \Delta(1, \beta, \beta^2) = -7 \cdot 97.
\]

Since this is squarefree, Prop. 4.8 tells us that \( \{1, \beta, (\beta')^2\} \) is an integral basis and \( \Delta_F = -7 \cdot 97 \).

**Example.** Consider the field \( F = \mathbb{Q}(i, \sqrt{d}) \), where \( d \) is a squarefree integer with \( d \equiv 1 \mod 4 \). We readily see that \( [F : \mathbb{Q}] = 4 \) and that \( \{1, i, \sqrt{d}, i\sqrt{d}\} \) is a basis consisting of integral elements. Rather than first going to a primitive element, we may directly compute \( \Delta(1, i, \sqrt{d}, i\sqrt{d}) \) with the aid of Prop. 3.4(i). But before we even begin computing, we see that the chosen basis is not going to be optimal. Indeed, we know from Example 4.4 that \( \gamma := \frac{1}{2} + \frac{1}{2}\sqrt{d} \) is integral, and we are better off if we start our computations with the basis \( \{1, i, \gamma, i\gamma\} \), as Prop. 3.4(iii) gives that \( \Delta(1, i, \gamma, i\gamma) = 2^{-4} \cdot \Delta(1, i, \sqrt{d}, i\sqrt{d}) \).
Let $\gamma' = \frac{1}{2} - \frac{i}{2}\sqrt{d}$. Writing $|A|$ for the determinant of a matrix $A$, we have

$$
\begin{vmatrix}
1 & 1 & 1 & 1 \\
i & -i & i & -i \\
\gamma & \gamma & \gamma' & \gamma' \\
i\gamma & -i\gamma & i\gamma' & -i\gamma'
\end{vmatrix} = 
\begin{vmatrix}
-2i & 0 & -2i \\
0 & -\sqrt{d} & -\sqrt{d} \\
-2i\gamma & -i\sqrt{d} & -i \\
i\gamma & \sqrt{d} & i\gamma & -i\gamma'
\end{vmatrix} = -2i \cdot 
\begin{vmatrix}
-\sqrt{d} & -\sqrt{d} \\
-\sqrt{d} & i\sqrt{d}
\end{vmatrix} = -4d.
$$

This gives that $\Delta(1, i, \gamma, i\gamma) = 16d^2$.

In particular, the primes $p$ whose squares divide $\Delta(1, i, \gamma, i\gamma)$ are $p = 2$ and the primes dividing $d$. Given such a prime $p$, our task is to consider elements

$$
y = m_1 + m_2i + m_3\gamma + m_4i\gamma \quad \text{with } (m_1, \ldots, m_4) \in \{0, 1, \ldots, p - 1\}^4 \setminus \{(0, 0, 0, 0)\}, \quad (*)
$$

and to figure out whether or not $y/p$ is again integral. Even though we only need to consider coefficients $m_i \in \{0, 1, \ldots, p - 1\}$, this seems a lot of work. However, we may remark that $F/\mathbb{Q}$ is a Galois extension with $\text{Gal}(F/\mathbb{Q}) = \{\text{id}, \sigma, \tau, \sigma\tau\} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. Here $\sigma$ and $\tau$ are the automorphisms given by

$$
\sigma i = -i, \quad \sigma(\sqrt{d}) = \sqrt{d} \quad \text{and} \quad \tau i = i, \quad \tau(\sqrt{d}) = -\sqrt{d}.
$$

(So $\tau(\gamma) = \gamma'$.) Of course, the automorphisms of $F$ over $\mathbb{Q}$ map $O_F$ into itself.

Given $y$ as above, we have

$$
\sigma(y) = m_1 - m_2i + m_3\gamma - m_4i\gamma
$$

$$
\tau(y) = m_1 + m_2i + m_3\gamma' + m_4i\gamma'
$$

$$
\sigma\tau(y) = m_1 - m_2i + m_3\gamma' - m_4i\gamma'.
$$

Suppose $y/p$ is integral. Then $(y + \tau(y))/p = ((2m_1 + m_3) + (2m_2 + m_4)i)/p$ is integral, too. Since $\mathbb{Z}[i]$ is the ring of integers of $\mathbb{Q}[i]$, we find that $2m_1 + m_3 \equiv 0 \mod p$ and $2m_2 + m_4 \equiv 0 \mod p$.

Similarly, $(y + \sigma y)/p = ((2m_1 + m_3) + m_4i\sqrt{d})/p$ is integral. Since $-d \equiv 3 \mod 4$, Example 4.4 tells us that $\mathbb{Z}[\sqrt{d}]$ is the ring of integers of $\mathbb{Q}[i\sqrt{d}] = \mathbb{Q}[\sqrt{-d}]$. Hence we find that $2m_1 + m_3 \equiv 0 \mod p$ and $m_4 \equiv 0 \mod p$.

For $p = 2$ the conditions we have found give $m_3 = m_4 = 0$ (since $0 \leq m_i < p$), so $y = m_1 + m_2i$. Again using that $\mathbb{Z}[i]$ is the ring of integers of $\mathbb{Q}[i]$, we find that for $p = 2$ there are no elements $y$ as in $(*)$ such that $y/2$ is integral. If $p$ is an odd prime number the conditions we have found give $m_2 = m_4 = 0$, so $y = m_1 + m_3\gamma$. Since $\mathbb{Z}[\gamma]$ is the ring of integers of $\mathbb{Q}[\gamma] = \mathbb{Q}[\sqrt{d}]$ we find that for odd primes $p$ there are also no elements $y$ as in $(*)$ such that $y/p$ is integral.

Here the algorithm stops. As output it gives that $\{1, i, \gamma, i\gamma\}$ is an integral basis for $O_F$, and that $\Delta_F = 400$. 

29
Chapter 5. Dedekind rings.

In this chapter we introduce Dedekind rings (Richard Dedekind, German mathematician, 1831-1916). Rings of integers of number fields are important examples of Dedekind rings. We will show that the fractional ideals of a Dedekind ring admit unique factorization into prime ideals.

**Definition.** A commutative ring $R$ is called Noetherian if every sequence

$$I_1 \subset I_2 \subset \cdots \subset I_i \subset \cdots$$

of ideals of $R$ stabilizes, i.e., there is an index $i_0$ such that $I_i = I_{i_0}$ for all $i \geq i_0$.

**Lemma 5.1.** Let $R$ be a commutative ring. The following are equivalent:

(i) Every $R$-ideal is finitely generated.

(ii) $R$ is Noetherian.

(iii) Every non-empty collection $\Omega$ of $R$-ideals contains a maximal element, i.e., an ideal $I$ such that no ideal $J \in \Omega$ properly contains $I$.

**Proof.** (i) $\Rightarrow$ (ii) Let $I_1 \subset I_2 \subset \cdots \subset I_i \subset \cdots$ be a sequence of ideals of $R$. First we note that the union $I := \cup_{i \geq 1} I_i$ is again an ideal of $R$. Suppose $I$ is generated by $\alpha_1, \ldots, \alpha_m$. For every $\alpha_k$ there exists an index $i$ such that $\alpha_k \in I_i$. Writing $N$ for the maximum of the indices $i$, we see that $\alpha_k \in I_N$ for all $k$. Therefore $I = I_N$ and the sequence stabilizes.

(ii) $\Rightarrow$ (iii) Suppose $\Omega$ is a non-empty collection without maximal elements. Pick $I = I_1 \in \Omega$. Since $I_1$ is not maximal, there exists an ideal $I_2 \in \Omega$ such that $I_1 \subsetneq I_2$. Similarly, there exists an ideal $I_3 \in \Omega$ such that $I_2 \subsetneq I_3$. In this way we obtain a sequence $I_1 \subset I_2 \subset \cdots \subset I_i \subset \cdots$ that does not stabilize. This contradicts the fact that $R$ is Noetherian.

(iii) $\Rightarrow$ (i) Let $I$ be an ideal of $R$ and let $\Omega$ be the collection of ideals $J \subset I$ which are finitely generated. Since $(0) \in \Omega$, we see that $\Omega \neq \emptyset$ and hence contains a maximal element $J$. If $J \neq I$, we pick $x \in I \setminus J$ and we see that the ideal $J + (x)$ properly contains $J$ and is in $\Omega$. This contradicts the maximality of $J$. We conclude that $I = J$. \qed

Many rings that naturally appear in mathematics are Noetherian (Emmy Noether, German mathematician, 1882-1935). Every principal ideal ring is clearly Noetherian, so fields and the ring $\mathbb{Z}$ are Noetherian rings. According to Exercise 5.A., the quotient ring $R/I$ of a Noetherian ring $R$ is again Noetherian. Finite products of Noetherian rings are Noetherian. The famous “Basissatz” of Hilbert (David Hilbert, German mathematician, 1862-1943) says that the polynomial ring $R[T]$ is Noetherian whenever $R$ is. (Hilbert’s Basissatz can be found in most textbooks on commutative algebra, e.g. the book by Atiyah and MacDonald.)

Non-Noetherian rings are often very large. For instance, the ring $R[X_1, X_2, X_3, \ldots]$ of polynomials in countably many variables over a commutative ring $R$ is not Noetherian. But sometimes it can be rather hard to decide whether a given ring is Noetherian or not.

**Definition.** Let $R \subset S$ be an extension of commutative rings. An element $x \in S$ is called integral over $R$, if there exists amonic polynomial $f(T) \in R[T]$ with $f(x) = 0$. A domain $R$ is called integrally closed if every integral element in the field of fractions of $R$ is contained in $R$.

Using this terminology, one can say that the integers of number fields are, in fact, integers over $\mathbb{Z}$. Let $F$ be a number field. We will see in Chapter 6 that the ring of integers in $F$ is integrally closed. Other examples of integrally closed rings are provided by Exercise 5.D: every unique factorization domain is integrally closed. The ring $\mathbb{Z}[2i]$ is not integrally closed: the element $i$ is contained in its quotient field $\mathbb{Q}(i)$ but it is integral over $\mathbb{Z}$ and hence over $\mathbb{Z}[i]$. 30
Definition. Let $R$ be a commutative ring. The height of a prime ideal $p$ of $R$ is the supremum of the integers $n$ for which there exists a chain

$$p = p_0 \subseteq p_1 \subseteq p_2 \subseteq \cdots \subseteq p_n \subseteq R$$

of distinct prime ideals in $R$. The Krull dimension of a ring is the supremum of the heights of the prime ideals of $R$.

For example, a field has Krull dimension 0 and the ring $\mathbb{Z}$ has Krull dimension 1 (Wolfgang Krull, German mathematician, 1899–1970). In general, principal ideal rings that are not fields, have dimension 1. It is easy to show that for every field $K$, the ring of polynomials $K[X_1, \ldots, X_n]$ has dimension at least $n$ (and in fact, $\text{Kdim}(R) = n$). The notion of (Krull) dimension has its origin in algebraic geometry: the ring of regular functions on an affine variety of dimension $n$ over a field $K$ has Krull dimension equal to $n$.

Definition. A Dedekind ring is a Noetherian, integrally closed domain of dimension at most 1.

By Exercise 5.H, every principal ideal domain $R$ is a Dedekind ring. Its dimension is 0 if $R$ is a field and 1 otherwise. Not all Dedekind rings are principal ideal domains. In the next section we will prove that rings of integers of number fields are Dedekind rings.

Definition. Let $R$ be a Dedekind ring with field of fractions $K$. A fractional ideal of $R$ (or $K$) is an additive subgroup $I \subset R$ for which there exists $\alpha \in K$ such that $\alpha I$ is a non-zero ideal of $R$.

Proposition 5.2. Let $R$ be a Dedekind ring with field of fractions $K$. Then

(i) Every non-zero ideal of $R$ is a fractional ideal. A fractional ideal contained in $R$ is an ideal of $R$.

(ii) If $I$ and $J$ are fractional ideals, then $IJ := \{\sum_{i}^{\leq \infty} \alpha_i \beta_i \mid \alpha_i \in I, \beta_i \in J\}$ is again a fractional ideal.

(iii) For every $\alpha \in K^*$ the set $(\alpha) = \alpha R = \{\alpha r \mid r \in R\}$ is a fractional ideal. Such a fractional ideal is called a principal fractional ideal.

(iv) For every fractional ideal $I$, the set $I^{-1} = \{\alpha \in K \mid \alpha I \subset R\}$ is a fractional ideal.

Proof. (i) The first statement is obvious. If $I \subset R$ is a fractional ideal, then $\alpha I$ is an ideal for some $\alpha \in K^*$. It is straightforward to verify that this implies that already $I$ is an ideal.

(ii) If $\alpha I \subset R$ and $\beta J \subset R$ then $\alpha \beta I J \subset R$.

(iii) This follows from the fact that $\alpha^{-1}(\alpha) = R$.

(iv) Let $\alpha \neq 0$ be any element of $I$. Then $\alpha I^{-1} \subset R$ is an ideal. \qed

Theorem 5.3. Let $R$ be a Dedekind ring and let $\text{Id}(R)$ be the set of fractional ideals of $R$. Then

(i) The set $\text{Id}(R)$ is, with the multiplication of Prop. 5.2(ii), an abelian group. The neutral element is $R$ and the inverse of a fractional ideal $I$ is $I^{-1}$.

(ii) We have

$$\text{Id}(R) \cong \bigoplus_p \mathbb{Z}$$

where $p$ runs over the non-zero prime ideals of $R$. More precisely: every fractional ideal can be written, in a unique way, as a finite product of prime ideals (with exponents in $\mathbb{Z}$).

Proof. Since the theorem is trivial when $R$ is a field, we will suppose that $R$ is not a field. We suppose, in other words, that $R$ has Krull dimension 1.

(i) We observe that the multiplication defined in Prop. 5.2(ii) is associative and commutative since the multiplication in $R$ is. It is very easy to verify that $RI = I$ for every fractional ideal $I$. 31
In step (4) of the proof of part (ii) we show that for every fractional ideal \( I \), its inverse is given by \( I^{-1} \).

(ii) The proof is given in six steps:

1. Every non-zero ideal of \( R \) contains a product of non-zero prime ideals of \( R \).

   Suppose that there exists an ideal that does not contain a product of non-zero prime ideals. So, the collection \( \Omega \) of such ideals is not empty. Since \( R \) is Noetherian, we can, by Lemma 5.1, find an ideal \( I \in \Omega \) such that every ideal \( J \) that properly contains \( I \) is not in \( \Omega \). Clearly \( I \) is not prime itself. Therefore there exist \( x, y \notin I \) such that \( xy \in I \). The ideals \( I + (x) \) and \( I + (y) \) are strictly larger than \( I \) and hence contain a product of non-zero prime ideals. Say \( p_1 \cdots p_r \subseteq I + (x) \) and \( p'_1 \cdots p'_s \subseteq I + (y) \). Now we have \( p_1 \cdots p_r p'_1 \cdots p'_s \subseteq (I + (x))(I + (y)) \subseteq I \), contradicting the fact that \( I \in \Omega \).

2. For every ideal \( I \) with \( 0 \neq I \neq R \) one has that \( R \subseteq I^{-1} \).

   Let \( m \) be a maximal ideal with \( I \subseteq m \subseteq R \). Since \( I^{-1} \supseteq m^{-1} \supseteq R^{-1} = R \) it suffices to prove the statement for \( I = m \) a maximal ideal. Let \( 0 \neq a \in m \). By part (i) there exist prime ideals \( p_i \) such that \( p_1 \cdots p_r \subseteq \langle a \rangle \). Let us assume that the number of prime ideals \( r \) in this product is minimal. Since \( m \) itself is a prime ideal, one of the primes \( p_i \), say \( p_1 \), is contained in \( m \). Since \( R \) has Krull dimension 1, we conclude that \( p_1 = m \). By minimality of \( r \) we see that \( p_2 \cdots p_r \not\subseteq \langle a \rangle \) and we can pick \( b \in p_2 \cdots p_r \) with \( b \notin \langle a \rangle \). So, \( b/a \notin R \), but \( b/a \in m^{-1} \) because \( bm \subseteq p_2 \cdots p_r m \subseteq \langle a \rangle \). This proves (2).

3. \( mm^{-1} = R \) for every maximal ideal \( m \subseteq R \).

   Since \( R \subseteq m^{-1} \) we have that \( m \subseteq mm^{-1} \subseteq R \). Suppose we had \( m = mm^{-1} \). Then every \( x \in m^{-1} \) satisfies \( xm \subseteq m \). Since \( m \) is finitely generated over \( R \), it follows from Exercise 5.5 that \( x \) is integral over \( R \). Since \( R \) is integrally closed this would imply that \( m^{-1} \subseteq R \), contradicting the conclusion of step (2). We conclude that \( m \neq mm^{-1} \) and hence that \( mm^{-1} = R \), as required.

4. \( II^{-1} = R \) for every fractional ideal \( I \).

   By definition, a fractional ideal is of the form \( I = bJ \) for some \( b \in K^* \) and some non-zero ideal \( J \subseteq R \). One readily sees that \( I^{-1} = b^{-1}J^{-1} \), and therefore \( II^{-1} = JJ^{-1} \). So it suffices to prove the assertion in case \( I \subseteq R \).

   Suppose there exist non-zero ideals \( I \) with \( II^{-1} \neq R \). Choose an \( I \) which is maximal with respect to this property. Let \( m \) be a maximal ideal containing \( I \). Since \( R \subseteq m^{-1} \), we have that \( I \subseteq Im^{-1} \subseteq m^{-1} \subseteq R \). We see that \( Im^{-1} \) is an ideal of \( R \). If we had \( Im^{-1} = I \), then by the same argument as in step (3) \( m^{-1} \) would be integral, which is not the case. Hence \( Im^{-1} \) is strictly larger than \( I \). Therefore \( Im^{-1}(Im^{-1})^{-1} = R \). This implies that \( m^{-1}(Im^{-1})^{-1} \subseteq I^{-1} \), so we get \( R = Im^{-1}(Im^{-1})^{-1} \subseteq II^{-1} \subseteq R \). Hence \( II^{-1} = R \), contradicting our choice of \( I \). This proves (4).

5. Every fractional ideal is a product of prime ideals with exponents in \( \mathbb{Z} \).

   Suppose \( I \subseteq R \) is an ideal which cannot be written as a product of prime ideals. Suppose that \( I \) is maximal with respect to this property. Let \( m \) be a maximal ideal \( I \subseteq m \subseteq R \). Then \( I \subseteq Im^{-1} \subseteq R \). By the same argument as in step (3) we see that \( m^{-1} \not\subseteq R \) implies that \( Im^{-1} \neq I \); hence \( Im^{-1} \) is strictly larger than \( I \). So \( Im^{-1} \) is a product of primes and therefore, multiplying by \( m \), so is \( I \). This contradiction shows that every integral ideal \( I \subseteq R \) is a product of prime ideals. By definition, every fractional ideal is of the form \( \alpha^{-1}I \) where \( \alpha \in R \) and \( I \) is an ideal of \( R \). We conclude that every fractional ideal is a product of prime ideals, with exponents in \( \mathbb{Z} \).

6. The decomposition into prime ideals is unique.
Suppose $\prod p^{\nu_p} = R$ with $\nu_p \neq 0$. This gives us a relation $I_p = J$ where $I$ and $J$ are ideals in $R$ and $J$ is a product of primes different from $p$. However, since $p$ is prime we have that $J \subseteq p$ and therefore $p$ contains a non-zero prime ideal different from itself. This is impossible. The proof of Theorem 5.3 is now complete. \hfill \Box

It is easy to see that the ideals of $R$ are precisely the fractional ideals that have a prime ideal decomposition $\prod p^{\nu_p}$ with non-negative exponents. When $R$ is a Dedekind ring, $p \subset R$ is a non-zero prime ideal, and $I$ is a fractional ideal, we denote by

$$\text{ord}_p(I)$$

the exponent $n_p$ of $p$ in the prime decomposition of $I$. For $x \in F^*$ we denote by

$$\text{ord}_p(x)$$

the exponent $\text{ord}_p((x))$ occurring in the prime decomposition of the principal fractional ideal $(x)$. The following corollary is a generalization of the important Lemma 1.2 used in the introduction.

**Corollary 5.4.** Let $R$ be a Dedekind domain, let $N \in \mathbb{Z}_{>0}$ and let $I_1, I_2, \ldots, I_m$ be non-zero ideals of $R$ which are mutually coprime, i.e., $I_i + I_j = R$ whenever $i \neq j$. If

$$I_1 I_2 \cdots I_m = J^N$$

for some ideal $J \subset R$, then there exists for every $1 \leq i \leq m$ an ideal $I_i$ such that $J_i^N = I_i$.

**Proof.** By Theorem 5.3 we can decompose the ideals $I_i$ into a product of distinct prime ideals $p_{i,j}$, say

$$I_i = \prod_{j=1}^{n_i} p_{i,j}^{\epsilon_{i,j}}.$$

Then

$$I_1 I_2 \cdots I_m = \prod_{i=1}^{m} \prod_{j=1}^{n_i} p_{i,j}^{\epsilon_{i,j}} = J^N.$$

Since the ideals $I_i$ are mutually coprime, all the prime ideals ideals $p_{i,j}$ are distinct. By Theorem 5.3, the group of fractional ideals is a sum of copies of $\mathbb{Z}$. We conclude that all the exponents $\epsilon_{i,j}$ are divisible by $N$ and hence that the ideals $I_i$ are $N$-th powers of ideals, as required. \hfill \Box

**Definition.** Let $R$ be a Dedekind ring with field of fractions $K$. We define a map

$$\theta: K^* \to \text{Id}(R)$$

by $\theta(\alpha) = (\alpha)$. The image of $\theta$ is the subgroup $\text{PId}(R)$ of principal fractional ideals and the kernel of $\theta$ is precisely the group of units $R^*$ of $R$. The cokernel of $\theta$ is called the class group of $R$:

$$\text{Cl}(R) = \text{coker}(\theta) = \text{Id}(R)/\text{PId}(R).$$

In other words, there is an exact sequence

$$0 \longrightarrow R^* \longrightarrow F^* \xrightarrow{\theta} \text{Id}(R) \longrightarrow \text{Cl}(R) \longrightarrow 0.$$

The class group of a Dedekind ring measures how far $R$ is from being a principal ideal domain. Fields and, more generally, principal ideal domains have trivial class groups. The analogue of the class group in algebraic geometry is the Picard group. For a smooth algebraic curve this is the

33
group of divisors modulo its subgroup of principal divisors. One can show [11], that every abelian group is isomorphic to the class group $\text{Cl}(R)$ of some Dedekind domain $R$. In Chapter 10 we show that the class groups of rings of integers of number fields are always finite.

**Proposition 5.5.** let $R$ be a Dedekind ring. The following are equivalent:

(i) The class group $\text{Cl}(R)$ is trivial.

(ii) Every fractional ideal of $R$ is principal.

(iii) $R$ is a principal ideal domain.

(iv) $R$ is a unique factorization domain.

**Proof.** The implications (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) $\Rightarrow$ (iv) are easy or standard. To prove that (iv) $\Rightarrow$ (i) we first note that by Theorem 5.3 it suffices to show that every prime ideal is principal. Let, therefore, $\mathfrak{p}$ be a non-zero prime ideal and let $0 \neq x \in \mathfrak{p}$. Writing $x$ as a product of irreducible elements and observing that $\mathfrak{p}$ is prime, we see that $\mathfrak{p}$ contains an irreducible element $\pi$. The ideal $(\pi)$ is a prime ideal. Since the ring $R$ is a Dedekind ring, it has Krull dimension 1 and we conclude that $\mathfrak{p} = (\pi)$ and hence that $\mathfrak{p}$ is principal, as required. □

This completes our discussion of Dedekind rings in general. In the next section we apply our results to a special class of Dedekind rings: rings of integers of number fields.

**Exercises**

(5.A) If $R$ is a Noetherian ring then for every ideal $I \subset R$, the ring $R/I$ is also Noetherian.

(5.B) Let $R$ be a Noetherian ring. Show, without invoking the Axiom of Choice, that every ideal is contained in a maximal ideal.

(5.C) Consider the ring $C^\infty(\mathbb{R}) = \{ f: \mathbb{R} \to \mathbb{R} \mid f \text{ is a } C^\infty\text{-function} \}$. Is this ring Noetherian?

(5.D) Show that every unique factorization domain is integrally closed.

(5.E) Let $R$ be an integrally closed domain and let $f \in R[X]$ be a monic irreducible polynomial. Show that $f(T)$ is irreducible over $K$, the field of fractions of $R$.

(5.F) Show: let $R \subset S$ be an extension of commutative rings. Then an element $x \in S$ is integral over $R$ if and only if there exists an $R$-module $M$ of finite type such that $xM \subset M$. (Hint: Copy the proof of Lemma 4.2).

(5.G) Consider the properties “Noetherian”, “integrally closed” and “of Krull dimension 1” that characterize Dedekind domains. Give examples of rings that have two of these properties, but not the third.

(5.H) Prove that every principal ideal domain is a Dedekind domain.

(5.I) Let $I$ and $J$ be two fractional ideals of a Dedekind domain.

(i) Show that $I \cap J$ and $I + J$ are fractional ideals.

(ii) Show that $I^{-1} + J^{-1} = (I \cap J)^{-1}$ and that $I^{-1} \cap J^{-1} = (I + J)^{-1}$.

(iii) Show that $I \subset J$ if and only if $J^{-1} \subset I^{-1}$.

(5.J) Let $R$ be a Dedekind ring. Show:

(i) for $\alpha \in R$ and a fractional ideal $I$ one has that $\alpha I \subset I$.

(ii) every fractional ideal $I$ is of the form $m^{-1}J$ where $m \in \mathbb{Z}$ and $J$ is an ideal of $R$.

(iii) if $I = (x)$ is a principal fractional ideal, then $I^{-1} = (x^{-1})$.

(5.K) Let $I$ and $J$ be fractional ideals of a Dedekind domain $R$. Let $n_p$ and $m_p$ be the exponents in their respective prime decompositions. Show that $I \subset J \iff n_p \geq m_p$ for all primes $p$.

(5.L) Let $R$ be a Dedekind ring with only finitely many prime ideals. Show that $R$ is a principal ideal ring. (Hint: Use the Chinese Remainder Theorem)

(5.M) Show that in a Dedekind ring every ideal can be generated by at most two elements.
(5.N) Let $R$ be a Dedekind ring. Show that every class in $\text{Cl}(R)$ contains an ideal of $R$.

(5.O) Let $R$ be a Dedekind ring with field of fractions $K$. Let $S$ be a set of prime ideals of $R$. Let $R' \subset K$ be the subset defined by

$$R' = \{x \in K^* | (x) = \prod p^{n_p} \text{ with } n_p \geq 0 \text{ for all } p \not\in S \} \cup \{0\}.$$  

Show that $R'$ is a Dedekind ring.

(5.P) Let $R$ be a Dedekind ring and let $p$ and $p'$ be two different non-zero prime ideals of $R$. Then $p + p' = R$.

(5.Q) Let $R \hookrightarrow S$ be an extension of Dedekind domains. Show that, if $S$ is an $R$-module of finite type, the canonical map $\text{Id}(R) \rightarrow \text{Id}(S)$ is injective.
Chapter 6. The Dedekind $\zeta$-function.

In this chapter we prove that the ring of integers of a number field is a Dedekind ring. We introduce the Dedekind $\zeta$-function associated to a number field.

**Proposition 6.1.** Let $F$ be a number field. Then the ring of integers $O_F$ of $F$ is a Dedekind ring.

**Proof.** By Cor. 4.6(ii), every ideal of $O_F$ is a finitely generated abelian group. From Lemma 5.1 we conclude that $O_F$ is a Noetherian ring. By Cor. 4.6(iii) every non-zero prime ideal is maximal. This implies that the Krull dimension of $O_F$ is at most 1.

It remains to be shown that $O_F$ is integrally closed. So, suppose $x \in F$ is integral over $O_F$, which means that it satisfies an equation $x^m + a_{m-1}x^{m-1} + \cdots + a_1x + a_0 = 0$, where the coefficients $a_j$ are in $O_F$. We want to show that $x \in O_F$. Let $\omega_1, \ldots, \omega_n$ be an integral basis for $O_F$. Let $M \subset F$ be the abelian subgroup generated by the elements

$$\omega_i \cdot x^j \quad \text{with } 1 \leq i \leq n \text{ and } 0 \leq j \leq m - 1.$$ 

By construction, $M$ is $\neq 0$ and finitely generated as a $\mathbb{Z}$-module. By Lemma 4.2 it therefore suffices to show that $xM \subset M$. For this we only need to verify that $\omega_ix^m \in M$ for every $i$. But this is clear from the relation $x^m = -(a_0 + a_1x + \cdots + a_{m-1}x^{m-1})$ and the fact that all coefficients $a_j$ are in $O_F$. \hfill $\Box$

**Proposition 6.2.** Let $F$ be a number field and let $I$ and $J$ be non-zero ideals of its ring of integers $O_F$. Then $N(IJ) = N(I)N(J)$.

**Proof.** By Theorem 5.3 it suffices to prove that for every non-zero prime ideal $p \subset O_F$ we have

$$N(IP) = N(I)N(p).$$

From the exact sequence

$$0 \longrightarrow I/IP \longrightarrow R/IP \longrightarrow R/I \longrightarrow 0$$

we deduce that all we have to show, is that $\#(I/IP) = \#(R/p)$. The group $I/IP$ is a vector space over the field $R/p$. By Theorem 5.3 one has $I \neq IP$, so $I/IP \neq (0)$. Let $W$ be a subspace of $I/IP$. The inverse image of $W$ in $I$ is an ideal $J \subset R$ with $IP \subset J \subset I$. This implies that $p \subset IJ^{-1} \subset R$ and hence that $JI^{-1} = p$ or $JI^{-1} = R$. In other words $J = IP$ or $J = I$ and hence $W = 0$ or $W = I/IPM$. So, apparently the vector space $I/IP$ has only trivial subspaces. It follows that its dimension is one. This proves the proposition. \hfill $\Box$

**Definition 6.3.** Let $F$ be a number field and let $I$ be a fractional ideal of $F$. Suppose $I = JK^{-1}$, where $J$ and $K$ are two ideals of $O_F$. We define the norm $N(I)$ of $I$ by

$$N(I) = N(J)/N(K).$$

We can write a fractional ideal $I$ in more than one way as the quotient of two ideals $J$ and $K$. By Prop. 6.2, the norm $N(J)$ is independent of the choice of $J$ and $K$, i.e., only depends on $I$ itself.

The next proposition is an application of the multiplicativity of the norm map.
Proposition 6.4. Let $F$ be a number field of degree $n$.

(i) For every non-zero prime ideal $p \subset O_F$ there exists a unique prime number $p$ such that $p$ divides $p$. The norm of $p$ is a power of $p$.

(ii) Let $p_1^{e_1} \cdots p_g^{e_g}$ be the prime decomposition of the ideal generated by $p$ in $O_F$. Then

$$
\sum_{i=1}^{g} e_if_i = n
$$

where for every $i$ the number $f_i$ is defined by $N(p_i) = p^{f_i}$.

(iii) For every prime number $p$ there are at most $n$ distinct prime ideals of $O_F$ dividing $p$.

(iv) There are only finitely many ideals with bounded norm.

**Proof.** (i) Let $p$ be a prime ideal. By Exercise 4.A there exists an integer $m \neq 0$ in $p$. Since $p$ is a prime ideal, it follows that $p$ contains a prime number $p$. So $p$ divides $p$ and by Prop. 6.2 the norm $N(p)$ divides $N(p) = p^n$. Moreover, as $N(p) > 1$ there cannot be two different prime numbers $p$ for which the previous conclusions hold.

(ii) This follows at once from the multiplicative of the norm, by taking the norm of the prime decomposition of $(p)$ in $O_F$.

(iii) This is immediate from (ii).

(iv) This follows from Theorem 5.3 and (iii). \qed

The number $f_i$ is called the **inertia index** and $e_i$ is called the **ramification index** of the prime ideal $p_i$. We will see in Chapter 9 that for almost all $p_i$, the index $e_i$ is equal to 1. The prime ideals $p_i$ for which $e_i > 1$ are called **ramified**. If for a prime $p$ and a number field $F$ of degree $n$ one has exactly $n$ primes $p_i$ that divide $p$, each necessarily having $e_i = f_i = 1$, then we say that $p$ is **totally split in $F$**. In this case the primes $p_i$ all have norm $p$. At the other extreme it may be the case that there is only one prime ideal $p$ dividing $p$. If, in this case $f_1 = 1$, then $e_1 = n$ and we say that $p$ is **totally ramified** in $F$ over $Q$. If, on the other hand, $e_1 = 1$ and $f_1 = n$, we say that the prime $p$ remains prime or is inert in $F$; note that in this case $p = (p)$.

**Example 6.5.** Let $F = Q(\sqrt{-5})$. By Example 4.4 the ring of integers of $F$ is equal to $Z[\sqrt{-5}]$. We will factor some small prime numbers into prime ideals.

First we study the prime 2. Since $O_F/(2) = Z[T]/(2, T^2+5) = F_2[T]/((T+1)^2)$ is not a domain, the ideal $(2)$ is not prime in $O_F$. The reciprocal image of the ideal $(T+1) \subset F_2[T]/((T+1)^2)$ under the quotient map $O_F \to O_F/(2)$ is $p_2 = (2, 1 + \sqrt{-5})$. It is easily checked that $p_2^2 = (2)$. This is the decomposition of $(2)$ as a product of prime ideals of $O_F$. We see that 2 is ramified.

The ideal $p_2$ cannot be generated by 1 element only: suppose $p_2 = (a)$ where $a = a + b \sqrt{-5}$ with $a, b \in Z$. Then $a$ divides both 2 and $1 + \sqrt{-5}$. By the multiplicity of the norm, this means that $N(a)$ divides both $N(2) = 4$ and $N(1 + \sqrt{-5}) = 6$. Therefore $N(a) = 1$ or 2. If $N(a) = 1$, the element $a$ would be a unit of $O_F$, which is impossible since $p_2$ has index 2 in $O_F$. So $N(a) = a^2 + 5b^2 = 2$. But this equation has no solutions with $a, b \in Z$.

Next consider the ideal $(3) \subset O_F$. Since $O_F/(3) = Z[T]/(3, T^2+5) = F_3[T]/((T+1)(T-1))$ is not a domain, we see that $(3)$ is not prime. In fact, the reciprocal images of the ideals $(T+1)$ and $(T-1)$ are prime ideals that divide $(3)$. We let $p_3 = (3, 1 + \sqrt{-5})$ and $p_3' = (3, -1 + \sqrt{-5})$ denote these ideals. Neither $p_3$ nor $p_3'$ are principal ideals. One verifies easily that $(3) = p_3p_3'$ which gives us the prime decomposition of $(3)$ in $O_F$. We find that the prime 3 is totally split in $F$.

One checks that 7 decomposes in a way similar to 3. The prime 11 remains prime since $O_F/(11) \cong F_{11}[T]/(T^2 + 5)$ and the polynomial $T^2 + 5$ is irreducible modulo 11. Hence the
prime 11 is inert in \( F \). The decomposition of the prime numbers less than or equal to 11 is given in the following table:

**Table.**

<table>
<thead>
<tr>
<th>( p )</th>
<th>( (p) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>( p_2^2 )</td>
</tr>
<tr>
<td>3</td>
<td>( p_3p_3 )</td>
</tr>
<tr>
<td>5</td>
<td>( p_5^2 )</td>
</tr>
<tr>
<td>7</td>
<td>( p_7p_7 )</td>
</tr>
<tr>
<td>11</td>
<td>(11)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>( p )</th>
<th>( (p) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( p_2 = (2, 1 + \sqrt{-5}) )</td>
<td></td>
</tr>
<tr>
<td>( p_3 = (3, 1 + \sqrt{-5}) ) and ( p_3' = (3, 1 - \sqrt{-5}) )</td>
<td></td>
</tr>
<tr>
<td>( p_5 = (\sqrt{-5}) )</td>
<td></td>
</tr>
<tr>
<td>( p_7 = (7, 3 + \sqrt{-5}) ) and ( p_7' = (7, -3 + \sqrt{-5}) )</td>
<td></td>
</tr>
</tbody>
</table>

11 is inert.

The number 6 has in the ring \( \mathbb{Z} [\sqrt{-5}] \) two distinct factorizations into irreducible elements:

\[
6 = 2 \cdot 3, \\
= (1 + \sqrt{-5})(1 - \sqrt{-5}).
\]

The factors have norms 4, 9, 6 and 6 respectively. They are irreducible, for if they were not, their divisors would necessarily have norm 2 or 3. But, as we have seen above, this is impossible because, for trivial reasons, the Diophantine equations \( a^2 + 5b^2 = 2 \) and \( a^2 + 5b^2 = 3 \) do not have any solutions \( a, b \in \mathbb{Z} \). There exists, however, a unique factorization of the ideal \( (6) \) in “ideal” prime factors. These prime factors are non-principal ideals. The factorization refines the two factorizations above:

\[
(6) = p_2^2p_3p_3'p_5.
\]

Indeed, one has, on the one hand that \( p_2^2 = (2) \) and \( p_3p_3' \) and on the other that \( p_2p_3 = (1 + \sqrt{-5}) \) and \( p_2p_5 = (1 - \sqrt{-5}) \).

Finally we will apply Theorem 5.3 to the \( \zeta \)-function \( \zeta_F (s) \) of a number field \( F \). First we consider the \( \zeta \)-function of Riemann (G.B. Riemann, German mathematician 1826-1866):

\[
\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} \quad \text{for } s \in \mathbb{C} \text{ with } \text{Re}(s) > 1.
\]

L. Euler (Swiss mathematician who lived and worked in Berlin and St. Petersburg, 1707-1783) found an expression for \( \zeta(s) \) in terms of an infinite product:

\[
\zeta(s) = \prod_{p \text{ prime}} \left( 1 - \frac{1}{p^s} \right)^{-1} = \prod_{p \text{ prime}} \left( \frac{1}{1 - p^{-s}} \right) \quad \text{for } s \in \mathbb{C} \text{ with } \text{Re}(s) > 1.
\]

Important remark: If we say that a product \( \prod a_i \) converges then we mean that the sum \( \sum \log(a_i) \) converges in the usual sense, and then of course we take the limit value of the product to be \( \exp(\sigma) \) with \( \sigma = \sum \log(a_i) \). In particular, the fact that we have an expansion of \( \zeta(s) \) as an Euler product implies at once that \( \zeta(s) \) does not have any zeroes in \( \mathbb{C} \) with real part larger than 1.

The proof of Euler’s formula is as follows: let \( s \in \mathbb{C} \text{ with } \text{Re}(s) > 1 \). Observe that

\[
\left(1 - \frac{1}{p^s}\right)^{-1} = 1 + \frac{1}{p^s} + \frac{1}{p^{2s}} + \frac{1}{p^{3s}} + \cdots
\]

38
Since every positive integer can be written as a product of primes in a unique way, we find that for every \( X \in \mathbb{R}_{>0} \) we have
\[
\prod_{p \leq X} \left(1 - \frac{1}{p^s}\right)^{-1} = \sum_{n} \frac{1}{n^s}
\]
where \( n \) runs over the positive integers that have only prime factors less than \( X \). Therefore
\[
\left| \sum_{n=1}^{\infty} \frac{1}{n^s} - \prod_{p \leq X} \left(1 - \frac{1}{p^s}\right)^{-1} \right| \leq \sum_{n>X} \frac{1}{n^\Re(s)}
\]
and this converges to 0 for \( X \to \infty \), as follows from the fact that the sum \( \sum_{n=1}^{\infty} 1/n^x \) converges for \( x \in \mathbb{R}_{>1} \). This implies Euler’s formula.

**Definition 6.6.** Let \( F \) be a number field. The Dedekind \( \zeta \)-function \( \zeta_F(s) \) is given by
\[
\zeta_F(s) = \sum_{I \neq 0} \frac{1}{N(I)^s}
\]
where \( I \) runs over the non-zero ideals of \( \mathcal{O}_F \). We see that for \( F = \mathbb{Q} \) the Dedekind \( \zeta \)-function \( \zeta_{\mathbb{Q}}(s) \) is just Riemann’s \( \zeta \)-function. We will now study for which \( s \in \mathbb{C} \) this sum converges.

**Proposition 6.7.** Let \( F \) be a number field. Then
\[
\zeta_F(s) = \sum_{I \neq 0} \frac{1}{N(I)^s} = \prod_{p} \left(1 - \frac{1}{N(p)^s}\right)^{-1}
\]
where \( I \) runs over the non-zero ideals of \( \mathcal{O}_F \) and \( p \) runs over the non-zero prime ideals of \( \mathcal{O}_F \). The sum and the product converge for \( s \in \mathbb{C} \) with \( \Re(s) > 1 \).

**Proof.** Let \( m \) be the degree of \( F \) and let \( s \in \mathbb{C} \) with \( \Re(s) > 1 \). By Prop. 6.4(iii) there are at most \( m \) prime ideals dividing a fixed prime number \( p \). Therefore
\[
\left| \sum_{N(p) \leq X} \frac{1}{N(p)^s} \right| \leq m \sum_{p \leq X} \frac{1}{p^\Re(s)} \leq m \sum_{n \leq X} \frac{1}{n^\Re(s)},
\]
where \( p \) runs over the primes of \( \mathcal{O}_F \) of norm at most \( X \), where \( p \) runs over the prime numbers at most \( X \), and where \( n \) runs over the integers from 1 to \( X \). Since the last sum converges for \( X \to \infty \), the first sum converges absolutely. Using Exercise 6.D we then find that the product
\[
\prod_{p} \left(1 - \frac{1}{N(p)^s}\right)^{-1}
\]
converges. Now we take \( s \in \mathbb{R}_{>1} \). By Theorem 5.3 the ideals \( I \) admit a unique factorization as a product of prime ideals. This implies
\[
\sum_{N(I) \leq X} \frac{1}{N(I)^s} \leq \prod_{p} \left(1 - \frac{1}{N(p)^s}\right)^{-1}
\]
and since the terms \( \frac{1}{N(I)^s} \) are positive, we see that the sum converges. Moreover
\[
\left| \sum_{I \neq 0} \frac{1}{N(I)^s} - \prod_{N(p) \leq X} \left(1 - \frac{1}{N(p)^s}\right)^{-1} \right| \leq \sum_{N(I)>X} \frac{1}{N(I)^\Re(s)}
\]

39
which converges to 0 for \( X \to \infty \). This concludes the proof.

\[ \square \]

**Exercises**

(6.A) Let \( F \) be a number field and let \( I \) be a fractional ideal of \( F \). Show that there is a positive integer \( m \) such that \( mI \) is an ideal.

(6.B) Show that the ideal \( I = (2, 2i) \subset \mathbb{Z}[2i] \) is not invertible, i.e., \( I^{-1} \neq R \).

(6.C) Let \( A \) be an additively written abelian group, which is free with basis \( \{ e_\lambda \}_{\lambda \in A} \). Let \( a_1, a_2, \ldots, a_m \in A \). Define the integers \( a_{i, \lambda} \) by \( a_i = \sum_{\lambda \in A} a_{i, \lambda} e_\lambda \). Suppose that for all \( i \neq j \), the sets \( \lambda \in \Lambda | a_{i, \lambda} \neq 0 \) and \( \lambda \in \Lambda | a_{j, \lambda} \neq 0 \) have empty intersection. Suppose that

\[
\sum_{i=1}^{m} a_i = N
\]

from some \( N \in \mathbb{Z}_{>0} \) and \( v \in A \). Show that \( N \) divides every \( a_{i, \lambda} \).

(6.D) Let \( a_i \in \mathbb{R}_{\geq 0} \) for \( i = 1, 2, \ldots \). Show that \( \sum_i a_i \) converges if and only if \( \prod_i (1 + a_i) \) converges.

(6.E) Show that \( \mathbb{Q}_p^* \) and the additive group of the ring \( \mathbb{Z}[T] \) are isomorphic as abelian groups.

(6.F) Let \( F \) be a number field of degree \( n \). Show that for every \( q \in \mathbb{Q}_p^* \), the fractional ideal generated by \( q \) has norm \( q^n \).

(6.G) Let \( F \) be a number field. For an ideal \( I \subset O_F \) we put \( \Phi(I) = \#(O_F / I)^* \). Show that \( \sum_{I \subset J \subset R} \Phi(J) = N(I) \prod_p (1 - N(p)^{-1}) \). Here the product runs over the prime ideals \( p \) with \( I \subset p \subset R \).

(6.H) Show that

\[
\zeta_{\mathbb{Q}(i)}(s) = \sum_{a, b \in \mathbb{Z}} \frac{1}{(a^2 + b^2)^s} \quad \text{for} \quad s \in \mathbb{C} \quad \text{with} \quad \text{Re}(s) > 1.
\]

(6.I) Show that the prime 2 is ramified in \( \mathbb{Q}(i) \). Show that a prime \( p > 2 \) splits completely in \( \mathbb{Q}(i) \) if and only if \( p \equiv 1 \pmod{4} \). Show that for every prime \( p \equiv 3 \pmod{4} \), the ideal \( (p) \) is a prime ideal of \( \mathbb{Z}[i] \).

(6.J) Show that

\[
\zeta_{\mathbb{Q}(i)}(s) = \left(1 - \frac{1}{2^s}\right)^{-1} \prod_{p \equiv 1 \pmod{4}} \left(1 - \frac{1}{p^s}\right)^{-2} \prod_{p \equiv 3 \pmod{4}} \left(1 - \frac{1}{p^s}\right)^{-1};
\]

here the products run over prime numbers \( p \) that are congruent to 1 and 3 modulo 4, respectively and \( s \in \mathbb{C} \) with \( \text{Re}(s) > 1 \).

(6.K) Show that

\[
\frac{\zeta_{\mathbb{Q}(i)}(s)}{\zeta_{\mathbb{Q}}(s)} = \prod_p \left(1 - \frac{\chi(p)}{p}\right)^{-1}
\]

where the product runs over the prime numbers \( p \), the complex number \( s \) has \( \text{Re}(s) > 1 \) and the function \( \chi \) is defined by

\[
\chi(p) = \begin{cases} 
1 & \text{if } p \equiv 1 \pmod{4}, \\
0 & \text{if } p = 2, \\
-1 & \text{if } p \equiv 3 \pmod{4}.
\end{cases}
\]

40
Chapter 7.  Finitely generated abelian groups.

The contents of the first part of this chapter are not of a number theoretical nature but the results will be very important in the sequel. We determine the structure of finitely generated abelian groups. We explain the relation between indices of finitely generated free groups and determinants.

An abelian group $G$ is said to be a free group of finite rank if $G \cong \mathbb{Z}^n$ for some $n$. The integer $n$ is then uniquely defined; it is called the rank of $G$.

For integers $a$ and $b$, the notation $a \mid b$ means that $a$ divides $b$.

**Theorem 7.1.** Let $G$ be a free abelian group of rank $n$ and let $H \subset G$ be a subgroup.

(i) The group $H$ is free of rank $m \leq n$.

(ii) There exists a $\mathbb{Z}$-basis $e_1, \ldots, e_n$ of $G$ and integers $a_1, \ldots, a_m \in \mathbb{Z}_{>0}$ such that $a_1|a_2|\cdots|a_m$ and such that $a_1e_1, \ldots, a_me_m$ is a basis for $H$. These integers $a_1, \ldots, a_m$ are uniquely determined by $H$.

**Proof.** Choose an isomorphism $G \cong \mathbb{Z}^n$. We may assume $0 \neq H \subset G$. Consider $\text{Hom}(G, \mathbb{Z})$, the group of homomorphisms $\varphi: G \to \mathbb{Z}$. Note that, via the chosen isomorphism $G \cong \mathbb{Z}^n$ we get $\text{Hom}(G, \mathbb{Z}) \cong \text{Hom}(\mathbb{Z}^n, \mathbb{Z}) \cong \mathbb{Z}^n$. Concretely: to $a = (a_1, \ldots, a_n) \in \mathbb{Z}^n$ we let correspond the homomorphism $f_a: \mathbb{Z}^n \to \mathbb{Z}$ given by $(x_1, \ldots, x_n) \mapsto a_1x_1 + \cdots + a_nx_n$.

Since $H \neq 0$ there exists a homomorphism $\varphi \in \text{Hom}(G, \mathbb{Z})$ and an element $h \in H$ such that $\varphi(h) > 0$. Now consider the set

$$\left\{ \varphi(h) \mid \varphi \in \text{Hom}(G, \mathbb{Z}), h \in H \right\} \subset \mathbb{Z},$$

and let $a_1$ be the smallest positive integer in this set. Further choose an element $h \in H$ and a homomorphism $\psi: G \to \mathbb{Z}$ such that $\psi(h) = a_1$.

We claim that $a_1$ divides $\varphi(h)$ for every $\varphi \in \text{Hom}(G, \mathbb{Z})$. To see this, let $d = \text{gcd}(a_1, \varphi(h))$ and take integers $u$ and $v$ with $ua_1 + v\varphi(h) = d$. This means that $d = (u\psi + v\varphi)(h)$, where we note that $u\psi + v\varphi$ is again in $\text{Hom}(G, \mathbb{Z})$. Since $0 < d \leq a_1$, it follows from our choice of $a_1$ that $d = a_1$. Hence $a_1$ divides $\varphi(h)$, as claimed. In particular, $a_1$ divides all coordinates of $h$. Hence we can define $e_1 = \frac{1}{a_1}h \in G$. We see that $\psi(e_1) = 1$ and we claim that

$$G = \mathbb{Z} \cdot e_1 \oplus \ker(\psi), \quad (1)$$

$$H = \mathbb{Z} \cdot a_1e_1 \oplus \left( \ker(\psi) \cap H \right). \quad (2)$$

The first decomposition says that every element $x \in G$ can uniquely be written as $x = re_1 + y$ for some $r \in \mathbb{Z}$ and $y \in \ker(\psi)$, and indeed, this holds with $r = \psi(x)$ and $y = x - re_1$. If $x \in H$ then $\psi(x) \in \mathbb{Z} \cdot a_1$ by definition of $a_1$, and then $y \in \ker(\psi) \cap H$.

For a subgroup $K \subset G$, let $\rho(K)$ be the maximal number of linearly independent elements in $K$, or, what is the same, the dimension of the $\mathbb{Q}$-subspace of $G \otimes \mathbb{Q} = \mathbb{Q}^n$ spanned by $K$. (A posteriori, $\rho(K)$ is of course nothing but the rank of $K$.)

Now we prove (i) by induction on $m = \rho(H)$. If $\rho(H) = 0$ then $H = \{0\}$ (since $G$ has no elements of finite order), and the claim is trivially true. If $m > 0$, we can decompose $G$ and $H$ as above. It follows from (2) that $\rho(\ker(\psi) \cap H) < \rho(H)$. By induction it then follows that $\ker(\psi) \cap H$ is free, and consequently $H$ is free as well. This proves (i).

Part (ii) is proved by induction on $n$. If $n = 0$ the statement is trivially true. If $n > 0$ then $\ker(\psi)$ is free, by (i), and by (1) its rank is $n - 1$. Hence we can apply induction, and we find that there exist a basis $e_2, \ldots, e_n$ for $\ker(\psi)$ and integers $a_2|a_3|\cdots|a_m$ such that $a_2e_2, \ldots, a_me_m$ is a basis for $\ker(\psi) \cap H$. But then it is clear from (1) and (2) that $e_1, e_2, \ldots, e_n$ is a basis of $G$ and that
$a_1 e_1, a_2 e_2, \ldots, a_m e_m$ is a basis of $H$. We further need to show that $a_1$ divides $a_2$. If $m = 1$ then there is no $a_2$ and the assertion is void, so we may assume $m > 1$. Consider the homomorphism $\varphi: G \to \mathbb{Z}$ given by $x_1 e_1 + \cdots + x_n e_n \mapsto x_1 + x_2$. We see that $a_1 = \varphi(a_1 e_1) \in \varphi(H)$. Now $\varphi(H) \subseteq \mathbb{Z}$ is an ideal, and by our choice of $a_1$ it follows that $a_1$ is the smallest positive integer in $\varphi(H)$. Hence $\varphi(H) = \mathbb{Z} \cdot a_1$. But also $a_2 = \varphi(a_2 e_2) \in \varphi(H)$; hence $a_1 | a_2$, as required.

We leave it to the reader to prove that the $a_i$ are unique.

**Corollary 7.2.**
(i) For any finitely generated abelian group $A$ there exist unique integers $r \geq 0$ and $a_1, a_2, \ldots, a_t \in \mathbb{Z}_{>1}$ satisfying $a_1 | a_2 | \cdots | a_t$ and such that

$$A \cong \mathbb{Z}^r \times \mathbb{Z}/a_1 \mathbb{Z} \times \cdots \times \mathbb{Z}/a_t \mathbb{Z}.$$  

(ii) For any finite abelian group $A$ there exist unique integers $a_1, a_2, \ldots, a_t \in \mathbb{Z}_{>1}$ with the property that $a_1 | a_2 | \cdots | a_t$, such that

$$A \cong \mathbb{Z}/a_1 \mathbb{Z} \times \cdots \times \mathbb{Z}/a_t \mathbb{Z}.$$  

(iii) Let $G \cong \mathbb{Z}^n$ be a free group of rank $n$ and let $H \subset G$ be a subgroup of $G$. Then $H$ has finite index in $G$ if and only if $\text{rk}(H) = \text{rk}(G)$.

**Proof.** (i) Let $A$ be a finitely generated group and let $n$ be an integer such that there is a surjective map

$$\theta: \mathbb{Z}^n \to A.$$  

By Theorem 7.1 there is a basis $e_1, \ldots, e_n$ of $\mathbb{Z}^n$ and there exist positive integers $a_1 | a_2 | \cdots | a_m$ such that $a_1 e_1, \ldots, a_m e_m$ is a basis for $H = \ker(\theta)$. It follows at once that

$$A \cong \mathbb{Z}^{n-m} \times \mathbb{Z}/a_1 \mathbb{Z} \times \cdots \times \mathbb{Z}/a_m \mathbb{Z}$$  

as required. The unicity of the numbers $a_i$ follows easily by considering $A$ modulo $a_i A$ for various $i$. (ii) This is a special case of (i). (iii) Choose a basis $e_1, \ldots, e_n$ of $G$ such that the subgroup $H$ has basis $a_1 e_1, \ldots, a_m e_m$. Then

$$G/H \cong \mathbb{Z}^{n-m} \times \mathbb{Z}/a_1 \mathbb{Z} \times \cdots \times \mathbb{Z}/a_m \mathbb{Z}$$

and clearly $\text{rk}(H) = \text{rk}(G)$ if and only if $n = m$ if and only if $[G: H] = \#(G/H)$ is finite.

**Corollary 7.3.** Let $M$ be a $n \times n$-matrix with integral coefficients. Let $G = \mathbb{Z}^n$ and let $H = M(G) \subset G$. Then

(i) The index of $H$ in $G$ is finite if and only if $\det(M) \neq 0$.

(ii) If $\det(M) \neq 0$ then $[G: H] = |\det(M)|$.

**Proof.** (i) According to Theorem 7.1 we can choose a basis $e_1, e_2, \ldots, e_n$ for $G$ and positive integers $a_1 | a_2 | \cdots | a_m$ such that $a_1 e_1, \ldots, a_m e_m$ is a basis for $H$. But then the integer $m \leq n$ is nothing but the rank of the matrix $M$. Combining this with Cor. 7.2(iii) we find

$$[G: H] < \infty \iff m = n \iff \det(M) \neq 0.$$  

(ii) Assume $\det(M) \neq 0$. Let $f: G \to G$ be the linear map defined by the matrix $M$, and let $M'$ be the matrix of $f$ with respect to the basis $e_1, \ldots, e_n$ as in (i). Then $M$ and $M'$ are conjugate.
matrices, so \( \det(M) = \det(M') \). Further, the matrix

\[
N = \begin{pmatrix}
a_1 & 0 \\
a_2 & \\
\vdots & \\
0 & a_n
\end{pmatrix}^{-1} \circ M'
\]

is invertible and has coefficients in \( \mathbb{Z} \), as it represents an isomorphism \( G \cong G' \). We have \( \det(M') = (a_1a_2 \cdots a_n) \cdot \det(N) \). But \( \det(N) = \pm 1 \) (Exercise 4.M) and \( a_1a_2 \cdots a_n = |G : H| \). \( \square \)

Next we apply the results on finitely generated abelian groups to number theory.

**Corollary 7.4.** Let \( f \in \mathbb{Z}[T] \) be a monic irreducible polynomial. Let \( \alpha \) denote a zero and let \( F = \mathbb{Q}(\alpha) \). Then the index \( [O_F : \mathbb{Z}[\alpha]] \) is finite and

\[
\text{Disc}(f) = [O_F : \mathbb{Z}[\alpha]]^2 \cdot \Delta_F.
\]

**Proof.** Let \( \omega_1, \ldots, \omega_n \) denote a \( \mathbb{Z} \)-basis for the ring of integers of \( F \). There is then a matrix \( M \) with integral coefficients such that

\[
M(\omega_1, \ldots, \omega_n) = (1, \alpha, \alpha^2, \ldots, \alpha^{n-1}).
\]

Therefore

\[
(\det(M))^2 \Delta_F = \Delta(1, \alpha, \alpha^2, \ldots, \alpha^{n-1})
\]

and hence, by Cor. 7.3 and Prop. 3.4(iii)

\[
[O_F : \mathbb{Z}[\alpha]]^2 \Delta_F = \text{Disc}(f),
\]

as required. \( \square \)

**Corollary 7.5.** Let \( F \) be a number field and let \( 0 \neq \alpha \in O_F \). Then the norm of the \( O_F \)-ideal generated by \( \alpha \) is equal to the absolute value of the norm of \( \alpha \):

\[
N((\alpha)) = |N(\alpha)|.
\]

**Proof.** Choose an integral basis \( \omega_1, \ldots, \omega_n \) for \( O_F \). Let \( M_\alpha \) denote the matrix which expresses the multiplication by \( \alpha \) with respect to this basis. Identifying \( O_F \cong \mathbb{Z}^n \) (as groups) via the chosen basis, we have \( (\alpha) = M_\alpha(O_F) \). Now

\[
|N(\alpha)| = |\det(M_\alpha)| \quad \text{by definition}
\]

\[
= [O_F : M_\alpha(O_F)] \quad \text{by Cor. 7.3}
\]

\[
= \#O_F/(\alpha) = N((\alpha)).
\]

This proves the corollary. \( \square \)

**Exercises**

(7.A) Let \( H = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \mathbb{Z} + \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \mathbb{Z} \subset \mathbb{Z}^2 \). Find a basis of \( \mathbb{Z}^2 \) as in Theorem 7.1.

(7.B) Let \( H \) in \( \mathbb{Z}^3 \) be the subgroup generated by \( (1, 1, 2) \), \( (5, 1, 1) \) and \( (-1, -5, -3) \). What is the structure of \( \mathbb{Z}^3/H \)?
(7.C) Let $R$ be a commutative ring. A module over $R$, or an $R$-module, is an abelian group equipped with a multiplication (by “scalars”) $R \times M \to M$ which satisfies the following axioms:

$$
a(x + y) = ax + ay,
\quad (a + b)x = ax + bx,
\quad (ab)x = a(bx),
\quad 1x = x,
$$

for $a, b \in R$ and $x, y \in M$.

(i) Show that a module over a field $R$ is the same as a vector space over $R$.

(ii) Show that every abelian group $G$ is a $\mathbb{Z}$-module with multiplication

$$nx = \begin{cases} x + x + \cdots + x & (n \text{ times}) \quad \text{if } n \geq 0, \\
-(x + x + \cdots + x) & (-n \text{ times}) \quad \text{if } n \leq 0,
\end{cases}$$

for $n \in \mathbb{Z}$ and $x \in G$. Conclude that a $\mathbb{Z}$-module is “the same” as an abelian group.

(7.D) Let $R$ be a commutative ring.

(i) Show that $R$ and, more generally, every ideal in $R$ is an $R$-module with the usual multiplication.

(ii) Let $M$ and $N$ be two $R$-modules. Show that the product $M \times N$ is an $R$-module with the multiplication:

$$a(x, y) = (ax, ay)$$

for $a \in R$ and $x, y \in R$.

(7.E) Let $R$ be a commutative ring and let $M$ be a module over $R$. A subgroup $N \subseteq M$ is called a submodule if $ax \in N$ for every $a \in R$ and $x \in N$, i.e., if $N$ is closed under the given scalar multiplication by elements of $R$. Note that a submodule is itself again an $R$-module for the scalar multiplication inherited from that on $M$.

(i) Show that every ideal $I$ of $R$ is a submodule of $R$.

(ii) Let $I$ be an ideal of $R$. Show that the quotient $R/I$ is an $R$-module with the multiplication

$$a(x + I) = ax + I$$

for every $a \in R$ and coset $a + I$ of $I$.

(iii) Let $M$ be an $R$-module and let $N \subseteq M$ be a submodule of $M$. Show that the quotient group $M/N$ is an $R$-module with multiplication

$$a(x + N) = ax + N$$

for every $a \in R$ and every coset $x + N$ of $N$ in $M$.

(7.F) Let $R$ be a commutative ring. An $R$-module is said to be finitely generated, if there is a finite number of elements $x_1, x_2, \ldots, x_t \in M$ such that every $m \in M$ can be written as

$$m = \lambda_1 x_1 + \lambda_2 x_2 + \cdots + \lambda_t x_t \quad \text{for some } \lambda_1, \lambda_2, \ldots, \lambda_t \in R.$$

(i) Show that the $R$-module $R^n = R \times \cdots \times R$ is finitely generated.

(ii) Show that an abelian group is finitely generated as a group if and only if it is finitely generated as a $\mathbb{Z}$-module.

(iii) Show: if $M$ is finitely generated and $N$ is a submodule of $M$, then $N/M$ is also finitely generated.

(iv) Give an example of a commutative ring $R$, a finitely generated $R$-module $M$, and an $R$-submodule $N \subseteq M$ which is not finitely generated.

(7.G) Prove the following generalization of Cor. 7.2: for every finitely generated $\mathbb{Z}[i]$-module $A$, there exist a unique integers $r \geq 0$ and elements $\alpha_1, \alpha_2, \ldots, \alpha_t \in \mathbb{Z}[i]$ satisfying $\alpha_1 | \alpha_2 | \cdots | \alpha_t$ and such that

$$A \cong \mathbb{Z}[i]^r \times \mathbb{Z}[i]/(\alpha_1) \times \cdots \times \mathbb{Z}[i]/(\alpha_t).$$

The elements $\alpha_i$ are unique up to multiplication by units of $\mathbb{Z}[i]$. 44
(7.H) Prove the following generalization of Cor. 7.2: let $F$ be a field. For every finitely generated $F[T]$-module $A$, there exist a unique integers $r \geq 0$ and unique monic polynomials $f_1, f_2, \ldots, f_r \in F[T]$ satisfying $f_1|f_2|\cdots|f_r$ and such that

$$A \cong F[T]^r \times F[T]/(f_1) \times \cdots \times F[T]/(f_r).$$

(7.I) Let $F$ be a field and let $n$ be a positive integer.

(i) Suppose that $F^n$ is an $F[T]$-module. Show that multiplication by $T$ is given by multiplication by an $n \times n$-matrix $M$ with coefficients in $F$.

(ii) Conversely, if $M$ is an $n \times n$-matrix with coefficients in $F$, then $F^n$ admits the structure of an $F[T]$-module, where multiplication by $T$ is given by multiplication by $M$.

*(7.J) (Theorem of Jordan-Hölder) Let $M$ be an $n \times n$-matrix with coefficients in $\mathbb{C}$. Show that $M$ is conjugate to a matrix of the form

$$
\begin{pmatrix}
(\ ) & 0 & \cdots & 0 \\
0 & (\ ) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & (\ )
\end{pmatrix}
$$

where the small “submatrices” have the form

$$
\begin{pmatrix}
\lambda & 1 & 0 & \cdots & 0 \\
0 & \lambda & 1 & \cdots & 0 \\
0 & 0 & \lambda & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \cdots & \lambda
\end{pmatrix}
$$

for some $\lambda \in \mathbb{C}$. (Hint. Turn $\mathbb{C}^n$ into a $\mathbb{C}[T]$-module by means of the matrix $M$. Then apply Exercise 7.H.)
Chapter 8. Lattices.

This chapter concerns lattices. Lattices are finitely generated groups with additional structure. Many of the finitely generated groups that arise in algebraic number theory are, in natural way, equipped with the structure of a lattice.

We show that the ring of integers $O_F$ of an algebraic number field $F$ admits a natural lattice structure. In Chapter 11 we will see that, in a certain sense, the unit group $O_F^*$ admits a lattice structure as well.

**Definition 8.1.** Let $V$ be a vector space over $\mathbb{R}$. A subset $L \subset V$ is called a lattice if there exist $e_1, \ldots, e_n \in L$ such that

(i) $L = \sum_i \mathbb{Z}e_i$,

(ii) The $e_i$ are a basis for $V$ over $\mathbb{R}$.

An easy example of a lattice is the group $\mathbb{Z}^n$ contained in the vector space $\mathbb{R}^n$. The following example is very important.

**Example 8.2.** Let $F$ be a number field. The image under $\Phi$ of the ring of integers $O_F$ of $F$ in $F \otimes \mathbb{R} = \mathbb{R}^3 \times \mathbb{C}^2$ is a lattice.

**Proof.** By Theorem 2.6 the map $\Phi$ maps a $\mathbb{Q}$-base of $F$ to an $\mathbb{R}$-base of $F \otimes \mathbb{R}$. In particular, every $\mathbb{Z}$-base of $O_F$ is mapped to an $\mathbb{R}$-base of $F \otimes \mathbb{R}$. This implies that $\Phi(O_F)$ is a lattice in $F \otimes \mathbb{R}$. □

**Proposition 8.3.** Let $V$ be a real vector space and let $L \subset V$ be a subgroup. Then the following are equivalent:

(i) $L$ is a lattice.

(ii) $L$ is discrete and cocompact.

(iii) $L$ generates $V$ over $\mathbb{R}$ and for every bounded set $B \subset V$ one has that $B \cap L < \infty$.

Note: We say that $L$ is discrete if the topology on $L$ induced by the Euclidean topology on $V$ is the discrete one; this just means that for every $x \in L$ there is an $\varepsilon > 0$ such that $|x - y| > \varepsilon$ for all $y \in L \setminus \{x\}$. We say that $L$ is cocompact if $V/L$ is compact for the quotient topology.

**Proof.** (i) $\Rightarrow$ (ii) The set $L$ is clearly discrete. We have that $V = \sum_i e_i \mathbb{R}$ and therefore $V/L$, being a continuous image of the compact space $\sum_i e_i[0, 1]$ is compact. In other words, $L$ is cocompact.

(ii) $\Rightarrow$ (iii) Suppose $L$ is discrete and cocompact. If the subspace $W \subset V$ generated by $L$ is not the whole of $V$ then $V/W$ is not compact. But the natural map $V/L \to V/W$ is continuous and surjective, and we get a contradiction with the fact that $V/L$ is compact. Hence $W = V$. If $B \subset V$ is bounded then $B \cap L$ is a bounded closed subset of $V$; hence it is compact. But the topology on $B \cap L$ is the discrete one, and of course a discrete topological space is compact if and only if it is finite.

(iii) $\Rightarrow$ (i) Since $L$ generates $V$ over $\mathbb{R}$, there is an $\mathbb{R}$-basis $e_1, \ldots, e_n$ of $V$ consisting of elements of $L$. The set $B = \sum_i e_i[0, 1]$ is bounded and therefore $L$ can be written as a finite union:

$$L = \bigcup_{x \in B \cap L} \left( x + \sum_i e_i \mathbb{Z} \right).$$

We conclude that the index $[L : \sum_i e_i \mathbb{Z}] = m$ is finite and that $mL \subset \sum_i e_i \mathbb{Z}$. By Theorem 7.1 the group $mL$ is free and by Cor. 7.2 it is of rank $n$. We conclude that $L$ is free of rank $n$ as well. This proves the proposition. □

46
Corollary 8.4. Let $F$ be a number field. The image of a fractional ideal $I$ under $\Phi: F \to F \otimes \mathbb{R}$ is a lattice.

Proof. Let $n \neq 0$ be an integer such that $nI$ is an ideal. Let $0 \neq m \in nI$ be an integer. We have that
\[ \frac{m}{n} O_F \subset I \subset \frac{1}{n} O_F. \]
Since the image of $O_F$ in $F \otimes \mathbb{R}$ is a lattice, so is the image of $qO_F$ for every $q \in \mathbb{Q}^*$. We conclude that $\frac{m}{n} O_F$ is cocompact, hence also $I$ is cocompact. Similarly, we see that $\frac{1}{n} O_F$ is discrete and therefore also $I$ is discrete. By Prop. 8.3 it follows that the image of $I$ is a lattice. \qed

Definition. Let $V$ be a real vector space provided with a Haar measure. Let $L \subset V$ be a lattice. The covolume $\text{covol}(L)$ of $L$ is defined by
\[ \text{covol}(L) = \text{vol}(V/L) \]
where the volume is taken with respect to the Haar measure induced on the quotient group $V/L$.

It is easy to see that the covolume of $L = \sum_i \mathbb{Z}v_i \subset \mathbb{R}^n$ is also the volume of a so-called fundamental domain of $V$ for $L$:
\[ \text{covol}(L) = \text{vol}\left( \{ \sum_{i=1}^n \lambda_i v_i \mid 0 \leq \lambda_i < 1 \} \right). \]

The only case we shall use is when the vector space $V$ has finite dimension and is equipped with an inner product $\langle , \rangle: V \times V \to \mathbb{R}$. This gives rise to a Haar measure on $V$. If $e_1, \ldots, e_n$ is an orthonormal basis then the hypercube $[0,1] \cdot e_1 + \cdots + [0,1] \cdot e_n$ has volume equal to 1. Unless indicated otherwise, we shall consider the vector space $\mathbb{R}^n$ with its standard inner product, for which the basis $e_1 = (1,0,\ldots,0), \ldots, e_n = (0,\ldots,0,1)$ is orthonormal. The corresponding volume form is of course just $dx_1 dx_2 \cdots dx_n$.

Lemma 8.5. Let $e_1, \ldots, e_n$ be the standard basis of $\mathbb{R}^n$, provided with the usual Haar measure. Let $M$ be an $n \times n$-matrix with real coefficients. Let $L$ be the subgroup generated by the image $M(e_1, \ldots, e_n)$ of the basis. Then
(i) $L$ is a lattice if and only if $\det(M) \neq 0$.
(ii) If $L$ is a lattice, then $\text{covol}(L) = |\det(M)|$.

Proof. Clearly $\det(M) \neq 0$ if and only if the vectors $M(e_1), \ldots, M(e_n)$ span $\mathbb{R}^n$ and, therefore, if and only if $L$ is a lattice. This proves (i).

Part (ii) is a standard fact from linear algebra: For any $n$ vectors $v_1, \ldots, v_n \in \mathbb{R}^n$ the parallelepiped $\{ \sum_{i=1}^n \lambda_i v_i \mid 0 \leq \lambda_i < 1 \}$ has volume $|\det(M)|$. \qed

For instance, the lattice $\mathbb{Z} \cdot \left( \frac{2}{3} \right) + \mathbb{Z} \cdot \left( \frac{1}{2} \right) \subset \mathbb{R}^2$ has covolume $|\det\left( \begin{array}{cc} 2 & 1 \\ 0 & -2 \end{array} \right)| = 4$. The next proposition gives the covolumes of the lattices $\Phi(O_F)$ and $\Phi(I)$ in $F \otimes \mathbb{R}$.

Proposition 8.6. Let $F$ be a number field of degree $n$. Let $r_1$ denote the number of distinct homomorphisms $F \to \mathbb{R}$ and $2r_2$ the number of remaining homomorphisms $F \to \mathbb{C}$.
(i) The covolume of the lattice $O_F$ or rather $\Phi(O_F)$ in $F \otimes \mathbb{R}$ is given by
\[ \text{covol}(O_F) = 2^{-r_2} |\Delta_F|^{1/2}. \]
(ii) Let $I$ be a fractional ideal, the covolume of $I$ in $F \otimes \mathbb{R}$ is given by
\[ \text{covol}(I) = N(I)2^{-r_3} |\Delta_F|^{1/2}. \]

47
**Proof.** (i) As usual we identify the 2-dimensional vector space $\mathbb{C}$ with $\mathbb{R}^2$ via $z \mapsto (\text{Re}(z), \text{Im}(z))$. In this way we have that $F \otimes \mathbb{R} \cong \mathbb{R}^n$ and we find that

$$
\Phi(O_F) = 
\begin{pmatrix}
\varphi_1(\omega_1) & \cdots & \text{Re}\varphi_k(\omega_1) & \text{Im}\varphi_k(\omega_1) & \cdots \\
\varphi_1(\omega_2) & \cdots & \text{Re}\varphi_k(\omega_2) & \text{Im}\varphi_k(\omega_2) & \cdots \\
\vdots & \ddots & \vdots & \vdots & \ddots
\end{pmatrix}
$$

where $\omega_1, \ldots, \omega_n$ denotes a $\mathbb{Z}$-basis for $O_F$ and the $\varphi_j$ denote the embeddings $F \hookrightarrow \mathbb{C}$ up to complex conjugation. In the proof of Theorem 2.6 the determinant of this $n \times n$-matrix has been calculated:

$$
|\det| = |(2i)^{-r_F} \det(\varphi_i(\omega_j))| = 2^{-r_F} |\Delta_F|^{1/2}
$$

and hence, by Lemma 8.5,

$$
covol(O_F) = 2^{-r_F} |\Delta_F|^{1/2}.
$$

(ii) Using the notation of part (i), let $I \neq 0$ be a fractional ideal in $O_F$. By Exercise 4.A there exists a non-zero integer $m$ such that $mI$ is an ideal in $O_F$. The ideal $mI$, being a subgroup of finite index of the free group $O_F$, is free of rank $n$. Let $A$ be a matrix with integral coefficients such that

$$
mI = A \begin{pmatrix} \omega_1 \\ \vdots \\ \omega_n \end{pmatrix}.
$$

By Cor. 7.3(ii) the absolute value of the determinant of $A$ is equal to $[O_F : mI] = N(mI) = m^n N(I)$. As in (i), we have that

$$
covol(mI) = |\det(A \cdot \Phi(O_F))| = m^n N(I) 2^{-r_F} |\Delta_F|^{1/2}.
$$

By Exercise 8.B we have that $\text{covol}(mI) = m^n \cdot \text{covol}(I)$, and the result follows. \qed

**Exercises**

(A) Let $L = \{(x,y,z) \in \mathbb{Z}^3 \mid 2x + 3y + 4z \equiv 0 \pmod{7}\}$. Show that $L \subset \mathbb{R}^3$ is a lattice. Find a $\mathbb{Z}$-basis and calculate its covolume.

(B) Let $L \subset \mathbb{R}^n$ be a lattice. Let $A$ be an invertible $n \times n$-matrix. Show that $A(L)$ is a lattice. Show that $\text{covol}(A(L)) = |\det(A)| \cdot \text{covol}(L)$. Let $m \in \mathbb{Z}_{>0}$; show that $\text{covol}(mL) = m^n \text{covol}(L)$.

(C) Identify the quaternions $\mathbb{H} = \{a + bi + cj + dk \mid a, b, c, d \in \mathbb{R}\}$ with $\mathbb{R}^4$ via $a + bi + cj + dk \leftrightarrow (a, b, c, d)$. What is the covolume of the ring of Hurwitz integers

$$
\mathbb{Z}[i,j,k, \frac{1 + i + j + k}{2}]
$$

in $\mathbb{H}$?

(D) Let $F$ be a number field. Suppose $R \subset F$ is a subring with the property that its image in $F \otimes \mathbb{R}$ is a lattice. Show that $R \subset O_F$.

(E) (Euclidean imaginary quadratic rings.) Let $F$ be an imaginary quadratic number field. We identify $O_F$ with its $\Phi$-image in $F \otimes \mathbb{R} = \mathbb{C}$.

- (i) Show that $O_F$ is Euclidean for the norm if and only if the disks with radius 1 and centers in $O_F$ cover $\mathbb{C}$.

- (ii) Show that $O_F$ is Euclidean for the norm if and only if $\Delta_F = -3, -4, -7, -8$ or $-11$.

48
(iii) For real quadratic fields $F$ (with $F \otimes \mathbb{R} = \mathbb{R}^2$) there is a similar result: the ring $O_F$ of integers of a real quadratic field $F$ is Euclidean for the norm if and only if $\Delta_F = 5, 8, 12, 13, 17, 21, 24, 28, 29, 33, 37, 41, 44, 57, 73$ or 76. This result is due to Chatland and Davenport [10] and much harder to prove. The following is easier: show that the rings of integers of the rings of integers of the quadratic fields $F$ with $\Delta_F = 5, 8$ and 12 are Euclidean for the norm.

*(8.F) Let $L$ be a free abelian group of rank $r$. Let $Q(x)$ be a positive definite quadratic form on $L$. Suppose that for every $B \in \mathbb{R}$ there are only finitely many $x \in L$ with $Q(x) < B$. Then there is an injective map $I : L \rightarrow \mathbb{R}^r$ such that $i(L)$ is a lattice and $\|i(x)\| = Q(x)$. Here $\|v\|$ denotes the usual length of a vector $v \in \mathbb{R}^r$.

(8.G) Let $L \subseteq \mathbb{R}^n$ be a lattice. Show that

$$\lim_{t \to \infty} \frac{1}{t^n} \cdot \# \{ (v_1, \ldots, v_n) \in L | \|v_i\| \leq t \text{ for all } 1 \leq i \leq n \} = \frac{2^n}{\text{covol}(L)}.$$ 

(8.H) Show that the rings $\mathbb{Z}[\zeta_3]$ and $\mathbb{Z}[\zeta_4]$ are Euclidean for the norm. It was shown by H.W. Lenstra [35,36] that the ring $\mathbb{Z}[\zeta_m]$ is Euclidean for the norm when $\varphi(m) \leq 10$ (except for the case $m = 16$, which was done by Ojala).
Chapter 9. Discriminants and ramification.

Any number field $F$ can be written as $\mathbb{Q}(\alpha)$ where $\alpha$ is an algebraic integer. Consequently, the ring $\mathbb{Z}[\alpha]$ is a subring of $O_F$, which is of finite index by Cor. 7.4. In this chapter we investigate under which conditions $\mathbb{Z}[\alpha] = O_F$, or more generally, which primes divide the index $[O_F : \mathbb{Z}[\alpha]]$. For primes that do not divide this index, one can find the prime ideals of $O_F$ that divide $p$ from the decomposition of $(f_{\text{min}}^* \mod p)$ in the ring $\mathbb{F}_p[T]$. This is the content of the Factorization Lemma.

**Theorem 9.1. (Factorization Lemma or Kummer’s Lemma)** Suppose $f \in \mathbb{Z}[T]$ is an irreducible polynomial. Let $\alpha$ denote a zero of $f$ and let $F = \mathbb{Q}(\alpha)$. Let $p$ be a prime number not dividing the index $[O_F : \mathbb{Z}[\alpha]]$. Suppose the polynomial $f$ factors in $\mathbb{F}_p[T]$ as

$$f(T) = h_1(T)^{e_1} \cdots h_g(T)^{e_g}$$

where the polynomials $h_1, \ldots, h_g$ are the distinct irreducible factors of $f$ modulo $p$. Let $g_i \in \mathbb{Z}[T]$ be a polynomial that reduces to $h_i$ modulo $p$. Then $p_i = (g_i(\alpha), p)$ is a prime ideal of $O_F$ with $N(p_i) = p^{\deg(h_i)}$, the primes $p_1, \ldots, p_g$ are distinct, and the prime factorization of the ideal $(p)$ in $O_F$ is given by

$$(p) = p_1^{e_1} \cdots p_g^{e_g}.$$ 

**Proof.** We first observe that

$$\mathbb{Z}[\alpha]/(g_i(\alpha), p) \cong \mathbb{F}_p[T]/(h_i(T), f(T)) = \mathbb{F}_p[T]/(h_i(T)) \cong \mathbb{F}_p^{\deg(h_i)}.$$ 

Let $d = [O_F : \mathbb{Z}[\alpha]]$. By assumption, $p$ does not divide $d$. Let $a, b \in \mathbb{Z}$ such that $ap + bd = 1$. We claim that the map

$$O_F/p_i \rightarrow \mathbb{Z}[\alpha]/(g_i(\alpha), p)$$

is an isomorphism of rings. (Note that $p_i$ is the ideal generated by $p$ and $g_i(\alpha)$ in $O_F$, not in $\mathbb{Z}[\alpha]$.) To prove our claim we first observe that the map is clearly well defined. It is a homomorphism since $(bdx)(bdy) - bdx = bdx(1 - bd) = bdxyp$ for $x, y \in O_F$ and this is $0$ modulo the ideal $(g_i(\alpha), p) \subset \mathbb{Z}[\alpha]$. The map is injective because if $bdx \in (g_i(\alpha), p)$ then $x = (ap + bd)x = apx + bdx \in p_i$. Finally, the map is surjective since any $x \in \mathbb{Z}[\alpha]$ satisfies $x = (ap + bd)x \equiv bdx$. We conclude that $p_i \subset O_F$ is a prime ideal of norm $p^{\deg(h_i)}$. Therefore

$$N\left(\prod_i p_i^{e_i}\right) = p^{\sum_i \deg(h_i)e_i} = p^n$$

where $n = \deg(f)$. On the other hand, we have that

$$\prod_i p_i^{e_i} = \prod_i (g_i(\alpha), p)^{e_i} \subset (p).$$

Since $N((p)) = p^n$, we conclude that $(p) = \prod_i p_i$. Finally, the ideals $p_i$ are mutually distinct since $(g_i(\alpha), g_j(\alpha), p) = O_F$ for $i \neq j$. This proves the theorem.

**Corollary 9.2.** Let $F$ be a number field. Let $\alpha \in O_F$ be an integral element that generates $F$ over $\mathbb{Q}$. If $p$ is a prime number that ramifies in $F$ then $p$ divides the discriminant $\Delta_F$ or $p$ divides the index $[O_F : \mathbb{Z}[\alpha]]$. In particular, only finitely many primes $p$ are ramified in $F$.

**Proof.** Suppose $p$ ramifies and does not divide the index $[O_F : \mathbb{Z}[\alpha]]$. Let $f = f_{\text{min}}$ and let $\tilde{f} = \prod_i h_i(T)^{e_i}$ be the prime decomposition of $\tilde{f} := (f \mod p)$ in $\mathbb{F}_p[T]$. By the Factorization Lemma 9.1, the exponents $e_i$ are the same as the exponents that occur in the prime factorization
of the ideal \( pO_F \). Hence the assumption that \( p \) is ramified means that there is an index \( i \) with \( e_i > 1 \). But then the discriminant of \( \tilde{f} \) is zero, and since \( \text{Disc}(f) \mod p = \text{Disc}(\tilde{f}) \) we conclude that \( p \) divides \( \text{Disc}(f) \). But by Cor. 7.4, \( \text{Disc}(f) = [O_F : \mathbb{Z}[\alpha]]^2 \cdot \Delta_F \), and since we have assumed that \( p \nmid [O_F : \mathbb{Z}[\alpha]] \) it follows that \( p \mid \Delta_F \). □

**Example.** Let \( F = \mathbb{Q}(\alpha) \) where \( \alpha \) is a zero of the polynomial \( f(T) = T^3 - T - 1 \). We have seen in Chapter 4 that the discriminant of \( f \) is \(-23\). Therefore the ring of integers of \( F \) is just \( \mathbb{Z}[\alpha] \). (Use Prop. 4.8.) By the Factorization Lemma, a prime number \( p \) factors in \( O_F = \mathbb{Z}[\alpha] \) in the same way as the polynomial \( f(T) = T^3 - T - 1 \) factors in the ring \( \mathbb{F}_p[T] \). Modulo 2 and 3, the polynomial \( f(T) \) is irreducible; we conclude that the ideals (2) and (3) in \( O_F \) are prime. Modulo 5 the polynomial \( f(T) \) has a zero and \( f \) factors as \( T^3 - T - 1 = (T - 2)(T^2 + 2T - 2) \) in \( \mathbb{F}_5[T] \). We conclude that \( (5) = \mathfrak{p}_5 \mathfrak{p}_{25} \) where \( \mathfrak{p}_5 = (5,\alpha - 2) \) is a prime of norm 5 and \( \mathfrak{p}_{25} = (5,\alpha^2 + 2\alpha - 2) \) is a prime of norm 25. The prime 7 is again prime in \( O_F \) and the prime 11 splits, like the prime 5, into a product of a prime of norm 11 and of one of norm 121. The following table contains this and some more factorizations of prime numbers. The indices denote the norms of the prime ideals. Notice the only ramified prime: 23. There are also primes that split completely in \( F \) over \( \mathbb{Q} \). The prime 59 is the smallest example.

**Table.**

\( \mathfrak{p}_{23} = (\alpha - 10,23) \) and \( \mathfrak{p}_{23}' = (\alpha - 3,23) \)

\( \mathfrak{p}_{59} = (\alpha - 4,59) \), \( \mathfrak{p}_{59}' = (\alpha - 13,59) \) and \( \mathfrak{p}_{59}'' = (\alpha + 17,59) \)

**Proposition 9.3.** Let \( p \) be a prime and let \( f(T) \in \mathbb{Z}[T] \) be an Eisenstein polynomial for the prime \( p \). Let \( \alpha \) be a zero of \( f \) and let \( F = \mathbb{Q}(\alpha) \) be the number field generated by \( \alpha \). Then \( p \nmid [O_F : \mathbb{Z}[\alpha]] \).

**Proof.** Write \( f(T) = T^n + a_{n-1}T^{n-1} + \cdots + a_1T + a_0 \). By Cor. 7.4 the index \( d := [O_F : \mathbb{Z}[\alpha]] \) is finite. Suppose \( p \) divides \( d \). Consider the ideal \( I \subseteq \mathbb{F}_p[T] \) given by

\[
I = \{ h \in \mathbb{F}_p[T] \mid \text{there exists a } g \in \mathbb{Z}[T] \text{ with } (g \mod p) = h \text{ and } g(\alpha) \in pO_F \} \\
= \{ h \in \mathbb{F}_p[T] \mid \text{for all } g \in \mathbb{Z}[T] \text{ with } (g \mod p) = h \text{ we have } g(\alpha) \in pO_F \}.
\]

Note that this is a well-defined ideal. Further note that \( I \) contains \( (f \mod p) = T^n \). Since \( p \) divides the index \( [O_F : \mathbb{Z}[\alpha]] \), there exists an element \( x \in O_F \setminus \mathbb{Z}[\alpha] \) such that \( px \in \mathbb{Z}[\alpha] \). Write \( px = \sum_{i=0}^{n-1} b_i\alpha^i \) where the \( b_i \) are integers, not all divisible by \( p \). This implies that \( \sum_{i=0}^{n-1} b_iT^i \) is a non zero polynomial contained in the ideal \( I \) and we see that the ideal \( I \) is a proper divisor of \( T^n \) in the PID \( \mathbb{F}_p[T] \). But this implies that \( T^{n-1} \in I \), which just means that \( p \) divides \( \alpha^{n-1} \).

We have the relation

\[-a_0 = \alpha^n + a_{n-1}\alpha^{n-1} + \cdots + a_2\alpha^2 + a_1\alpha.\]
Now $pa$ divides $\alpha^n$, because we have just shown that $p$ divides $\alpha^{n-1}$. Also $pa$ divides each term $a_j\alpha^j$ for $1 \leq j \leq n-1$, because $p \mid a_j$. So we conclude that $pa$ divides $\alpha_0$. Now write $b_0 := a_0 / p$. By definition of an Eisenstein polynomial, $b_0$ is an integer with $p \nmid b_0$. On the other hand, working in the ring $O_F$ we have found that $p$ divides $\alpha^{n-1}$ and that $a$ divides $b_0$. So $b_0^{n-1} / p$ lies in $\mathbb{Q} \cap O_F = \mathbb{Z}$. As this contradicts the fact that $p \nmid b_0$, we conclude that $p$ does not divide $d$. \hfill \Box

**Example 9.4.** Let $p^n$ be a power of a prime $p$. Then the ring of integers of $\mathbb{Q}(\zeta_p^n)$ is $\mathbb{Z}[\zeta_p^n]$.

**Proof.** Write $q = p^n$. Clearly $\mathbb{Z}[\zeta_q]$ is contained in the ring of integers of $\mathbb{Q}(\zeta_q)$. By Exercise 3.N, the discriminant of $\Phi_q(T)$ is a power of $p$. By Cor. 7.4 we see that the only prime that could divide the index $[O_F : \mathbb{Z}[\zeta_q]]$ is $p$. Consider the minimum polynomial

$$f_{\text{min}}^c(T) = \Phi_q(T) = T^{(p-1)p^{n-1}} + T^{(p-2)p^{n-1}} + \ldots + T^{p^{n-1}} + 1.$$ 

It is easy to see that $\Phi_q(T + 1)$ is an Eisenstein polynomial for the prime $p$. By Prop. 9.3 we then conclude that $p$ does not divide $[O_F : \mathbb{Z}[\zeta_q]]$. This completes the example. \hfill \Box

The following two theorems will not be used in the sequel. They are included because they give complete answers to natural questions and because the proofs can easily be given using only the theory we have developed so far. Theorem 9.5 is an extension of Prop. 9.3. Theorem 9.6 makes part of Cor. 9.2 more precise.

**Theorem 9.5.** (Dedekind’s Criterion.) Suppose $\alpha$ is an algebraic integer with minimum polynomial $f(T) \in \mathbb{Z}[T]$ over $\mathbb{Q}$. Let $F = \mathbb{Q}(\alpha)$. For $p$ a prime number, let $f_1, \ldots, f_g \in \mathbb{Z}[T]$ and $e_1, \ldots, e_g \in \mathbb{Z}_{\geq 1}$ be such that $\tilde{f} = f_1^{e_1} \cdots f_g^{e_g}$ is the decomposition of $\tilde{f} = f \mod p$ into distinct irreducible polynomials modulo $p$. Then

$$p \text{ divides the index } [O_F : \mathbb{Z}[\alpha]]$$

if and only if there is an index $j$ such that $e_j \geq 2$ and

$$f_j \text{ divides } \left( \frac{f(T) - \prod_j f_j(T)^{e_j}}{p} \right) \text{ in } \mathbb{F}_p[T].$$

**Proof.** We put

$$u(T) = \frac{f(T) - \prod_j f_j(T)^{e_j}}{p} \in \mathbb{Z}[T],$$

and for every index $j$ we define the polynomial $F_j(T) \in \mathbb{Z}[T]$ by

$$F_j(T) = \frac{1}{f_j(T)} \prod_{j=1}^g f_j(T)^{e_j}.$$ 

Finally we let

$$x_j = \frac{1}{p} F_j(\alpha) = \frac{u(\alpha)}{f_j(\alpha)} \in F.$$ 

“If”: Suppose that $f_j(T)$ divides $u(T)$ in $\mathbb{F}_p[T]$ and that $e_j \geq 2$ for some index $j$. Consider $x = x_j$. Clearly $px \in \mathbb{Z}[\alpha]$, but since $\deg(F_j) < \deg(f)$, we have that $x \notin \mathbb{Z}[\alpha]$. To prove that $p$ divides the index $[O_F : \mathbb{Z}[\alpha]]$ it suffices to show that $x \in O_F$. Consider the ideal $I = (f_j(\alpha), p) \subset \mathbb{Z}[\alpha]$. We have that $xp = F_j(\alpha)$ which is a $\mathbb{Z}[\alpha]$-multiple of $f_j(\alpha)$ because $e_j \geq 2$. We have that $xf_j(\alpha) = u(\alpha)$ which is a $\mathbb{Z}[\alpha]$-multiple of $f_j(\alpha)$ by assumption. The ideal $I$ is a finitely generated abelian group. Lemma 3.1(iii) implies that $x$ is integral. This proves the sufficiency.
only if”: Suppose that \( p \) divides the index of \( \mathbb{Z}[\alpha] \) in \( \mathcal{O}_F \). Consider the \( \mathbb{F}_p[T] \)-ideal \( J = \{ h \in \mathbb{F}_p[T] \mid \frac{1}{p}h(\alpha) \in \mathcal{O}_F \} \). This ideal clearly contains \( f(T) \), but, by our assumption on the index, it is strictly larger than \( (f) \). Let \( \varphi \) be a generator of \( J \) and let \( j \) be an index such that

\[
f_j(T) \text{ divides } \frac{f(T)}{\varphi(T)} \quad \text{in } \mathbb{F}_p[T].
\]

We claim that this index \( j \) satisfies the conditions of the theorem. To show this we consider again

\[ x = x_j = \frac{1}{p}F_j(\alpha) = \frac{u(\alpha)}{f_j(\alpha)}. \]

Since \( \varphi \) divides \( F_j \), we have that \( x \in \mathcal{O}_F \). We conclude that there exists a monic polynomial in \( \mathbb{Z}[T] \) with \( u(\alpha)/f_j(\alpha) \) as a zero. Therefore \( f_j(\alpha) \) divides \( u(\alpha)^m \) in \( \mathbb{Z}[\alpha] \) for some integer \( m \geq 1 \). We conclude that there exists polynomials \( h_1, h_2 \in \mathbb{Z}[T] \) such that

\[ u(T)^m = f_j(T)h_1(T) + f(T)h_2(T) \]

and hence that \( f_j(T) \) divides \( u(T)^m \) in the ring \( \mathbb{F}_p[T] \). Since \( f_j(T) \) is irreducible modulo \( p \), this implies that \( f_j(T) \) divides \( u(T) \) modulo \( p \). It remains to prove that \( e_j \geq 2 \). From \( f_j(\alpha)x = u(\alpha) \) one concludes that \( F_j(x) + f_j(\alpha)x = F_j(\alpha) + u(\alpha) \) and hence that

\[ x = \frac{u(\alpha) + F_j(\alpha)}{p + f_j(\alpha)}. \]

Exactly the same proof as before, now gives that \( f_j(T) \) divides \( u(T) + F_j(T) \) modulo \( p \). Therefore \( f_j(T) \) divides \( F_j(T) \) and \( e_j \geq 2 \) as required. \( \square \)

**Theorem 9.6.** (R. Dedekind 1920) Let \( F \) be a number field and let \( p \) be a prime. Then \( p \) is ramified in \( F \) over \( \mathbb{Q} \) if and only if \( p \) divides \( \Delta_F \).

**Proof.** We introduce a slightly more general concept of “discriminant”: let \( K \) be a field and let \( A \) be a commutative \( K \)-algebra that is \( n \)-dimensional as a vector space over \( K \). (Note: \( \lambda(ab) = (\lambda a)b = a(\lambda b) \) for all \( a, b \in A \) and \( \lambda \in K \).) In Chapter 2 we have studied the special case \( K = \mathbb{Q} \) and \( A = F \) a number field.

On \( A \) we define the trace \( \text{Tr}(x) \) of an element \( x \in A \) by \( \text{Tr}(x) = \text{Tr}(M_x) \) where \( M_x : A \to A \) denotes the map given by \( a \mapsto xa \). For \( \omega_1, \ldots, \omega_n \in A \) we let

\[ \Delta(\omega_1, \ldots, \omega_n) = \det(\text{Tr}(\omega_j \omega_i))_{1 \leq i, j \leq n}. \]

In contrast to what we have seen in Chapter 3 or Exercise 3.L, in general it may happen that \( \Delta(\omega_1, \ldots, \omega_n) = 0 \) even if the \( \omega_i \) constitute a \( K \)-basis for \( A \). However, if this happens, it happens for every basis of \( A \): as in Chapter 3, the discriminant \( \Delta(\omega_1, \ldots, \omega_n) \) of a basis \( \omega_1, \ldots, \omega_n \) depends on the basis, but whether the discriminant is zero or not doesn’t: the discriminant differs by a multiplicative factor \( \det(M)^2 \) where \( M \in \text{GL}_n(K) \) is the matrix transforming one basis into the other. Using the fact that the non-nullity of the discriminant of a basis does not depend on the basis, we define the discriminant of \( A \) by

\[ \Delta(A/K) = \Delta(\omega_1, \ldots, \omega_n) \]

for some \( K \)-basis \( \omega_1, \ldots, \omega_n \) of \( A \). It is only well defined up to a element in \( (K^*)^2 \).
In Exercise 9.H it is shown that for two finite dimensional \( K \)-algebras \( A \) and \( B \) one has that
\[
\Delta(A \times B/K) = \Delta(A/K)\Delta(B/K).
\]

Now we start the proof. Let \( F \) be a number field of degree \( n \) and let \( p \) be a prime number. Consider the field \( K = \mathbb{F}_p \) and the \( n \)-dimensional \( K \)-algebra \( O_F/(p) \). We are going to calculate the discriminant of \( O_F/(p) \). First by reducing a \( \mathbb{Z} \)-basis of the ring of integers \( O_F \) modulo \( p \):
\[
\Delta(O_F/(p)/\mathbb{F}_p) \equiv \Delta_F \pmod{p}.
\]
Next we decompose \( O_F/(p) \) into a product of \( \mathbb{F}_p \)-algebras. Suppose \( p \) factors in \( O_F \) as
\[
(p) = p^{e_1}_1 \cdots p^{e_g}_g.
\]
By the Chinese Remainder Theorem (Exercise 4.G) we have that
\[
O_F/(p) \cong O_F/p^{e_1}_1 \times \cdots \times O_F/p^{e_g}_g
\]
and hence that
\[
\Delta(O_F/(p)) = \Delta((O_F/p^{e_1}_1)/\mathbb{F}_p) \cdots \Delta((O_F/p^{e_g}_g)/\mathbb{F}_p).
\]
By Exercise 2.Q the discriminant \( \Delta(\mathbb{F}_q/\mathbb{F}_p) \) is non-zero for every finite field extension \( \mathbb{F}_q \) of \( \mathbb{F}_p \). This shows that \( p \) does not divide \( \Delta_F \) whenever \( p \) is not ramified.

To show the converse, it suffices to show that \( \Delta((O_F/p^e)/\mathbb{F}_p) = 0 \) whenever \( p \) divides \( p \) and \( e > 1 \). Let therefore \( e > 1 \) and put \( A = O_F/p^e \) and let \( \pi \) be an element in \( p \) but not in \( p^2 \). Then \( \pi \) is nilpotent. Since it is not zero, we can use it as the first element in an \( \mathbb{F}_p \)-basis \( \omega_1, \ldots, \omega_k \) of \( A \). Clearly \( \pi \omega_i \) is nilpotent for every \( \omega_i \in A \). Since a nilpotent endomorphism has only eigenvalues 0, we see that the first row of the matrix \( (\text{Tr}(\omega_i \omega_j))_{1 \leq i, j \leq n} \) is zero. This concludes the proof of the theorem.

Results such as the preceding Theorems can be used to develop faster algorithms (i.e., faster than the one described in the Appendix to Chap. 4) to compute the ring of integers and the discriminant of \( F \). For more details about such algorithms, see for instance the book \textit{A course in computational algebraic number theory} by H. Cohen.

**Exercises**

(9.A) Let \( F = \mathbb{Q}(\alpha) \), where \( \alpha \) is a zero of the polynomial \( T^3 - T - 1 \). Show that the ring of integers of \( F \) is \( \mathbb{Z}[\alpha] \). Find the factorizations in \( \mathbb{Z}[\alpha] \) of the primes less than 10.

(9.B) Let \( d \) be a squarefree integer and let \( F = \mathbb{Q}(\sqrt{d}) \) be a quadratic field. Show that for odd primes \( p \) one has that \( p \) splits (is inert, ramifies) in \( F \) over \( \mathbb{Q} \) if and only if \( d \) is a square (non-square, zero) modulo \( p \).

(9.C) Let \( \zeta_5 \) denote a primitive 5th root of unity. Determine the decomposition into prime factors in \( \mathbb{Q}(\zeta_5) \) of the primes less than 14.

(9.D) Show that the following three polynomials have the same discriminant:
\[
T^3 - 18T - 6, \\
T^3 - 36T - 78, \\
T^3 - 54T - 150.
\]
Let \( \alpha, \beta \) and \( \gamma \) denote zeroes of the respective polynomials. Show that the fields \( \mathbb{Q}(\alpha), \mathbb{Q}(\beta) \) and \( \mathbb{Q}(\gamma) \) have the same discriminants, but are not isomorphic. (Hint: the splitting behavior of the primes is not the same.)

(9.E) Show that \( \mathbb{Z}[\sqrt[3]{20}, \sqrt[5]{50}] \) is the ring of integers of \( F = \mathbb{Q}(\sqrt[3]{20}, \sqrt[5]{50}) \). Show there is no \( \alpha \in O_F \) such that \( O_F = \mathbb{Z}[\alpha] \).

*(9.F) (Samuel) Let \( f(T) = T^3 + T^2 - 2T + 8 \in \mathbb{Z}[T] \). Show that \( f \) is irreducible.

(i) Show that \( \text{Disc}(f) = -4 \cdot 503 \). Show that the ring of integers of \( F = \mathbb{Q}(\alpha) \) admits \( 1, \alpha, \beta = (\alpha^2 - \alpha)/2 \) as a \( \mathbb{Z} \)-basis.

(ii) Show that \( O_F \) has precisely three distinct ideals of index 2. Conclude that 2 splits completely in \( F \) over \( \mathbb{Q} \).

(iii) Show that there is no \( \alpha \in F \) such that \( O_F = \mathbb{Z}[\alpha] \). Show that for every \( \alpha \in O_F - \mathbb{Z} \), the prime 2 divides the index \([O_F : \mathbb{Z}[\alpha]]\).

*(9.G) Let \( m \in \mathbb{Z}_{>0} \). Let \( K \) be a field, let \( A \) be the \( K \)-algebra \( K[T]/(T^m) \). Compute the discriminant of \( A \).

*(9.H) Let \( K \) be a field and let \( A \) and \( B \) be two finite dimensional \( K \)-algebras. Show that \( \Delta(A \times B) = \Delta(A) \times \Delta(B) \).
Chapter 10. The Theorem of Minkowski.

In this chapter we prove the most important finiteness results of algebraic number theory. We prove that the class group of the ring of integers is finite. This result is due to P. Lejeune Dirichlet (German mathematician, 1805–1859). We will prove it by means of techniques from the “Geometry of Numbers”, a subject created by Hermann Minkowski (German mathematician, 1864–1909) [41,42]. For a very thorough discussion of the geometry of numbers and its history see the book by Lekkerkerker and Gruber [34].

**Theorem 10.1.** (Minkowski’s convex body theorem) Let \( V \cong \mathbb{R}^n \) be a real vector space and let \( L \subset V \) be a lattice. Let \( X \) be a bounded, convex, symmetric subset of \( V \). If
\[
\operatorname{vol}(X) > 2^n \operatorname{covol}(L)
\]
then there exists a non-zero vector \( \lambda \in L \cap X \).

**Proof.** Consider the measure preserving natural map
\[
X \to V/2L.
\]
Since \( \operatorname{covol}(2L) = 2^n \operatorname{covol}(L) \) we see that \( \operatorname{vol}(X) > \operatorname{vol}(V/2L) \). Therefore there are two points \( x_1 \neq x_2 \) in \( X \) which have the same image in \( V/2L \). In other words \( x_1 - x_2 \in 2L \). We conclude that \( 0 \neq y = (x_1 - x_2)/2 \in L \). By symmetry we have that \( -x_2 \in X \) and hence, by convexity, that \( y = (x_1 - x_2)/2 \in X \). So \( 0 \neq y \in X \cap L \) as required. \( \square \)

In the proof of the following lemma, we will calculate a certain volume. This will be useful in the proof of Theorem 10.3.

**Lemma 10.2.** Let \( r_1, r_2 \in \mathbb{Z}_{>0} \) and put \( n = r_1 + 2r_2 \). For \( R \geq 0 \) put
\[
W(r_1, r_2, R) = \{(x_1, \ldots, x_{r_1}, y_1, \ldots, y_{r_2}) \in \mathbb{R}^{r_1} \times \mathbb{C}^{r_2} \mid |x_1| + \cdots + |x_{r_1}| + 2|y_1| + \cdots + 2|y_{r_2}| \leq R \}.
\]
Then
\[
\operatorname{vol}(W(r_1, r_2, R)) = 2^{r_1} \left( \frac{\pi}{2} \right)^{r_2} \frac{R^n}{n!}.
\]

**Proof.** The proof is by induction with respect to \( n \). If \( r_1 = 1 \) and \( r_2 = 0 \) and if \( r_1 = 0 \) and \( r_2 = 1 \), the result is easily verified. We will next discuss the two steps \( r_1 \to r_1 + 1 \) and \( r_2 \to r_2 + 1 \).

Case \( r_1 \to r_1 + 1 \):
\[
\operatorname{vol}(W(r_1 + 1, r_2, R)) = \int_{-R}^R \operatorname{vol}(r_1, r_2, R - |t|) \, dt
\]
\[
= 2^{r_1} \left( \frac{\pi}{2} \right)^{r_2} \frac{1}{n!} \int_{-R}^R (R - |t|)^n \, dt
\]
\[
= 2^{r_1+1} \left( \frac{\pi}{2} \right)^{r_2} \frac{1}{n!} \int_0^R t^n \, dt
\]
\[
= 2^{r_1+1} \left( \frac{\pi}{2} \right)^{r_2} \frac{R^{n+1}}{(n + 1)!}.
\]
Case \( r_2 \to r_2 + 1 \):
\[
\text{vol}(W(r_1, r_2 + 1, R)) = \int_{z \in \mathbb{C}} \text{vol}(r_1, r_2, R - |z|) d\mu(z)
\]
\[
= \int_0^{2\pi} \int_0^{R/2} 2^{r_2} \left( \frac{\pi}{2} \right)^{r_2} \frac{1}{n!} (R - 2\rho)^n \rho \, d\rho \, d\varphi
\]
\[
= 2\pi 2^{r_1} \left( \frac{\pi}{2} \right)^{r_2} \frac{1}{n!} \int_0^R t^n (R - t) \frac{dt}{2}
\]
\[
= 2^{r_1} \left( \frac{\pi}{2} \right)^{r_2} \frac{R^{n+2}}{(n + 2)!}.
\]
This proves the lemma. \( \square \)

**Theorem 10.3.** (H. Minkowski) Let \( F \) be a number field of degree \( n \). Let \( r_1 \) denote the number of embeddings \( F \hookrightarrow \mathbb{R} \) and \( 2r_2 \) the number of embeddings \( F \hookrightarrow \mathbb{C} \). Then every non-zero ideal \( I \) of \( O_F \) contains an element \( x \) with
\[
|N(x)| \leq \frac{n!}{\pi^n} \left( \frac{4}{\pi} \right)^{r_2} |\Delta_F|^{1/2} N(I).
\]

**Proof.** We view the ideal \( I \) via the map \( \Phi: O_F \to V_F \) as a lattice in \( V_F = \mathbb{R}^{r_1} \times \mathbb{C}^{r_2} \). By Prop. 8.6(ii) the covolume of \( I \) in \( V_F \) is
\[
\text{covol}(I) = 2^{-r_2} N(I) |\Delta_F|^{1/2}.
\]
For any positive real number \( R \) we put
\[
X(R) = \{(x_1, \ldots, x_{r_1}, y_1, \ldots, y_{r_2}) \in \mathbb{R}^{r_1} \times \mathbb{C}^{r_2} \mid |x_1| + \cdots + |x_{r_1}| + 2|y_1| + \cdots + 2|y_{r_2}| \leq R \}.
\]
Using the triangle inequality one easily verifies that \( X(R) \) is a convex, symmetric and bounded set.

By Lemma 10.2 its volume is given by
\[
\text{vol}(X(R)) = \frac{R^n}{n!} \left( \frac{\pi}{2} \right)^{r_2} 2^{r_1}.
\]

From Minkowski’s convex body Theorem 10.1 we conclude that if
\[
\frac{R^n}{n!} \left( \frac{\pi}{2} \right)^{r_2} 2^{r_1} > 2^n \cdot 2^{-r_2} N(I) |\Delta_F|^{1/2}
\]
then there exists a non-zero element \( x \in I \cap X(R) \). Since for every \( R \) the set \( X(R) \) is bounded, and since the set \( I \cap X(R) \) is finite, it follows that there is a vector \( x \in I \) such that \( x \in X(R) \) for every \( R \) satisfying (1). Since \( X(R) \) is closed for every \( R \), this vector \( x \) is also contained in \( X(R_0) \) where \( R_0 \) satisfies the equality
\[
\frac{R_0^n}{n!} \left( \frac{\pi}{2} \right)^{r_2} 2^{r_1} = 2^n \cdot 2^{-r_2} N(I) |\Delta_F|^{1/2}.
\]

57
By Prop. 3.2(iii) and the arithmetic-geometric-mean-inequality (Exercise 10.D), we have that
\[
|N(x)| = |x_1| \cdots |x_{r_1}| \cdot |y_1| \cdots |y_{r_2}|^2 \\
\leq \left( \frac{\left( |x_1| + \cdots + |x_{r_1}| + 2|y_1| + \cdots + 2|y_{r_2}| \right)^n}{n} \right)^n \\
\leq \frac{R^n}{n^n} = \frac{n!}{n^n} \left( \frac{4}{\pi} \right)^{r_2} |\Delta_F|^{1/2} N(I)
\]
as required. \hfill \Box

**Corollary 10.4.** Let $F$ be a number field of degree $n$.

(i) We have
\[
|\Delta_F| \geq \left( \frac{n^n}{n!} \left( \frac{\pi}{4} \right)^{r_2} \right)^2.
\]

(ii) We have $|\Delta_F| \geq \frac{\pi^2}{4}$. In particular, $|\Delta_F| > 1$ whenever $F \neq \mathbb{Q}$.

(iii) Every ideal class contains an ideal $I$ with
\[
|N(I)| \leq \frac{n!}{n^n} \left( \frac{4}{\pi} \right)^{r_2} |\Delta_F|^{1/2}.
\]

(iv) The class group $\text{Cl}(O_F)$ is finite.

**Proof.** (i) It follows from the multiplicity of the norm (Prop. 6.2) that for every ideal $I$ and $x \in I$, one has that $|N(x)| \geq N(I)$. Combining this with Theorem 10.3 gives (i).

(ii) One verifies (by induction) that $n^n \geq 2^{n-1}n!$ for all $n \geq 1$. It follows from (i) that
\[
|\Delta_F| \geq \left( \frac{n^n}{n!} \right)^2 \left( \frac{\pi}{4} \right)^{2r_2} \geq (2^{n-1})^2 \left( \frac{\pi}{4} \right)^n = \frac{\pi^n}{4^n}.
\]

(iii) Let $c$ be an ideal class. Every ideal class contains an integral ideal, so we can pick an integral ideal $J$ in the inverse of the class $c$. By Theorem 10.3 there exists an element $x \in J$ with
\[
|N(xJ^{-1})| \leq \frac{n!}{n^n} \left( \frac{\pi}{4} \right)^{-r_2} |\Delta_F|^{1/2}.
\]
Since the ideal $xJ^{-1}$ is integral and in $c$, the result follows.

(iv) By Prop. 6.3(iii) there are only a finite number of prime ideals of a given norm. Therefore, for every number $B$, there are only a finite number of integral ideals of norm less than $B$. The result now follows from (iii). \hfill \Box

The cardinality of the class group $\text{Cl}(O_F)$ is called the class number of $O_F$, or of $F$. It is denoted by
\[
h_F = \# \text{Cl}(O_F).
\]

The expression
\[
\frac{n!}{n^n} \left( \frac{4}{\pi} \right)^{r_2} \sqrt{|\Delta_F|}
\]
associated to a number field $F$, with the usual notations, is called the Minkowski constant associated to $F$. Although $n!/n^n \approx e^{-n} \sqrt{2\pi n}$, it grows rapidly with the degree $n$ of $F$. 58
The estimate in Cor. 10.4(i) can be drastically improved when the degree $n$ is large. We only mention the most recent asymptotic estimates, i.e., when $n \to \infty$, since these are the easiest to state. Using Stirling’s formula it is easy to see that Cor. 10.4(i) implies that

$$
|\Delta_F|^{1/n} \geq \left( \frac{e^{2\pi}}{4} \right) ^{n/2} \geq (5.803)(1.273)^{n/2}.
$$

Using the Dedekind $\zeta$-function $\zeta_F(s)$ of the number field $F$ and especially its functional equation (see Chapter 13) these estimates were improved by A.M. Odlyzko in 1976:

$$
|\Delta_F|^{1/n} \geq (4\pi e^\gamma) e^{\frac{1}{2n}},
$$

$$
\geq (22.37)(2.718)^{\frac{n}{2}}.
$$

Here $\gamma = 0.57721566490153 \ldots$ is Euler’s constant:

$$
\gamma = \lim_{n \to \infty} \left( \sum_{k=1}^{n} \frac{1}{k} - \log(n) \right).
$$

Odlyzko’s estimates are even better if the truth of certain generalized Riemann hypotheses (GRH) is assumed. See Serre’s Note [48] and Poitou’s Bourbaki talk [44] for more details.

$$
|\Delta_F|^{1/n} \geq (8\pi e^\gamma) (e^{\frac{1}{2n}})^{(8\pi e^\gamma)} \geq (44.76)(4.810)^{\frac{n}{2}} \quad \text{(GRH)}.
$$

J. Martinet [39] exhibited an infinite number of totally complex fields $F$ (i.e., fields with $r_2 = 0$), with $|\Delta_F|^{1/n} = 2^{3/2}11^{4/5}23^{4/5} = 92.37\ldots$. This indicates that Odlyzko’s bounds are close to being optimal.

Odlyzko’s methods can be used to obtain estimates for discriminants of number fields of finite degree as well. This has been done by F. Diaz y Diaz, who published his results in a table [14].

Minkowski’s Theorem can be used to calculate class groups of rings of integers of number fields. In the next section we will give some elaborate examples. Here we give two small examples.

**Examples.** (i) Take $F = \mathbb{Q}(\alpha)$ where $\alpha$ is a zero of the polynomial $f(T) = T^3 - T - 1$. In Chapter 4 we have calculated the discriminant $\Delta_F$ of $F$. We have that $\Delta_F = \text{Disc}(f) = -23$. It is easily verified that the polynomial $T^3 - T - 1$ has precisely one real zero. So $r_1 = 1$ and $r_2 = 1$. The bound in Minkowski’s Theorem is now

$$
\frac{3!}{3^3} \left( \frac{4}{\pi} \right) \sqrt{23} \approx 1.356942.
$$

Therefore, by Cor. 10.4(iii), every ideal class contains an integral ideal of norm less than or equal to 1. This shows, at once, that the class group of $F$ is trivial. (By Exercise 10.R the ring of integers $\mathbb{Z}[\alpha]$ is even Euclidean!)

(ii) Take $F = \mathbb{Q}(\sqrt{-47})$. By Examples 4.4 and 4.7 the ring of integers of $F$ is $\mathbb{Z}[\frac{1+\sqrt{-47}}{2}]$ and the discriminant of $F$ is $\Delta_F = -47$. Since $r_1 = 0$ and $r_2 = 1$ we find that the Minkowski constant is equal to

$$
\frac{2!}{2^2} \left( \frac{4}{\pi} \right) \sqrt{47} \approx 4.36444.
$$
Therefore the class group is generated by the prime ideals of norm less than or equal to 4. To find these prime ideals explicitly, we decompose the primes 2 and 3 in \( O_F \). Let \( \alpha = \frac{1 + \sqrt{-17}}{2} \). Then \( \alpha^2 - \alpha + 12 = 0 \). By the Factorization Lemma (Theorem 9.1) we see that \( (2) = p_2p_2' \) where \( p_2 = (2, \alpha) \) and \( p_2' = (2, \alpha - 1) \). Similarly \( (3) = p_3p_3' \) where \( p_3 = (3, \alpha) \) and \( p_3' = (3, \alpha - 1) \). We conclude that the only ideals of \( O_F \) of norm less than 4.36444 are \( O_F, p_2, p_2', p_3, p_3', p_2^2, p_2'^2, \) and \( p_2p_2' \). Therefore the class number is at most 8.

Since \( (2) = p_2p_2' \), the ideal classes of \( p_2 \) and \( p_2' \) are each others inverses: \( p_2' \sim p_2^{-1} \). Similarly \( p_3' \sim p_3^{-1} \). We conclude that the class group is generated by the classes of \( p_2 \) and \( p_3 \).

In order to determine the class group, we decompose some principal ideals into prime factors. Principal ideals \( (\beta) \) can be factored, by first factoring their norm \( N(\beta) \in \mathbb{Z} \) and then determining the prime ideal divisors of \( (\beta) \). For the sake of convenience we take elements \( \beta \) of the form \( \beta = \alpha - k \) where \( k \in \mathbb{Z} \) is a small integer. By Exercise 2.F we have that \( N(\beta) = N(k - \alpha) = k^2 - k + 12 \).

We find

<table>
<thead>
<tr>
<th>( k )</th>
<th>( \beta = \alpha - k )</th>
<th>( N(\beta) = k^2 - k + 12 )</th>
<th>( (\beta) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>(i)</td>
<td>1 ( - \alpha )</td>
<td>12 = 2^2 \cdot 3</td>
<td>( p_2^2p_3 )</td>
</tr>
<tr>
<td>(ii)</td>
<td>2 ( - \alpha )</td>

<td>32 = 2^5</td>
<td>( p_2^5 )</td>
</tr>
</tbody>
</table>

From entry (i), we see that the ideal class of \( p_2^2p_3' \sim (1) \) is trivial. The relation implies that \( p_3 \sim p_2^{-1} \).

We conclude that the class group is cyclic. It is generated by the class of \( p_2 \). We will now determine the order of this class. The second entry tells us that \( p_7 \sim p_2^{-1} \) and is not of much use to us. Relation (iii) implies that \( p_2 \sim p_2^2 \).

Combining this with the relation obtained from the first entry of our table, gives at once that \( p_2^5 \sim 1 \).

This relation can also be deduced directly from entry (v) of the table. It follows that the class group is cyclic of order 5 or 1. The latter case occurs if and only if the ideal \( p_2 \) is principal. Suppose that for \( a, b \in \mathbb{Z} \) the element \( \gamma = a + b(1 + \sqrt{-47})/2 \in O_F \) is a generator of \( p_2 \). Since the norm of \( p_2 \) is 2, we must have that

\[
2 = N(p_2) = |N(\gamma)| = a^2 + ab + 12b^2.
\]

Writing this equation as \((2a + b)^2 + 47b^2 = 8\), it is immediate that there are no solutions \( a, b \in \mathbb{Z} \). We conclude that \( p_2 \) is not principal and that \( \text{Cl}(\mathbb{Q}(\sqrt{-47})) \cong \mathbb{Z}/5\mathbb{Z} \).

**Corollary 10.6. (Ch. Hermite, French mathematician, 1822-1901) For any integer \( \Delta \), there are only finitely many number fields \( F \), up to isomorphism, with \( |\Delta_F| = \Delta \).**

**Proof.** Let \( \Delta \in \mathbb{Z} \). By Cor. 10.4(ii) there are only finitely many possible values for the degree \( n \) of a number field \( F \) with \( \Delta_F = \Delta \). There is, therefore, no loss in assuming that the degree \( n \) is fixed.
Let $F$ be a number field of degree $n$ and discriminant $\Delta$. Claim: there exists an element $\alpha \in O_F$ with $F = \mathbb{Q}(\alpha)$ and such that $|\varphi_i(\alpha)| < 1 + \sqrt{|\Delta|}$ for all embeddings $\varphi_i : F \to \mathbb{C}$.

Let us first show how the theorem follows from this claim. If $\alpha$ is as in the claim, we have $F \cong \mathbb{Q}[T]/(f)$ with $f = f_{\text{min}}^\alpha = f_{\text{char}}^\alpha$. The complex zeroes of $f$ are $\varphi_1(\alpha), \ldots, \varphi_n(\alpha)$, and by assumption these are bounded in absolute size by $1 + \sqrt{|\Delta|}$. Since the coefficients of $f$ can be expressed as symmetric polynomials in the zeroes $\varphi_i(\alpha)$, it follows that there is a number $b(n, \Delta) \in \mathbb{R}_{>0}$, depending only on $n$ and $\Delta$, such that all coefficients $a_j$ of $f$ have $|a_j| \leq b(n, \Delta)$. On the other hand, $\alpha \in O_F$, so all coefficients $a_j$ are integers. It follows that there are only finitely many possibilities for $f$ and therefore, up to isomorphism, for $F$.

To prove the claim, consider the bounded, symmetric and convex box $B$ in $F \otimes_{\mathbb{Q}} \mathbb{R} \cong \mathbb{R}^n \times \mathbb{C}^n$ given by

\[
B = \begin{cases} 
(x_1, \ldots, x_{r_1+r_2}) & |x_1| < 1 + \sqrt{|\Delta|} \text{ and } |x_i| < 1 \text{ for } i \neq 1 & \text{if } r_1 > 0, \\
(x_1, \ldots, x_{r_1+r_2}) & |\text{Re}(x_1)| < 1, |\text{Im}(x_1)| < 1 + \sqrt{|\Delta|} \text{ and } |x_i| < 1 \text{ for } i \neq 1 & \text{if } r_1 = 0.
\end{cases}
\]

It is easily checked that the volume of $B$ is $\pi^{n-1}(1 + \sqrt{|\Delta|})$ if $r_1 = 0$ and $2^{r_1} \pi^n (1 + \sqrt{|\Delta|})$ otherwise. In each case, $\text{vol}(B)$ exceeds $2^n \text{covol}(O_F)$. By Minkowski’s Theorem 10.1, there exists $0 \neq \alpha \in O_F$ such that

\[\Phi(\alpha) = (\varphi_1(\alpha), \ldots, \varphi_{r_1}(\alpha), \varphi_{r_1+1}(\alpha), \ldots, \varphi_{r_1+r_2}(\alpha)) \in B.\]

Since $\alpha \neq 0$, we have that $N(\alpha) \geq 1$. Since $\Phi(\alpha) \in B$, we have that $|\varphi_i(\alpha)| < 1$ for all $i > 1$. We conclude that $|\varphi_1(\alpha)| \geq 1$.

It remains to be shown that $F = \mathbb{Q}(\alpha)$. By Prop. 3.2, $f_{\text{char}}^\alpha(T) = \prod_{i=1}^n (T - \varphi_i(\alpha))$ equals $(f_{\text{min}}^\alpha)^m$ with $m = [F : \mathbb{Q}(\alpha)]$. We claim that $\varphi_1(\alpha) \neq \varphi_i(\alpha)$ for any $i \geq 2$. This is immediate if $r_1 > 0$, for in that case all $\varphi_i(\alpha)$ with $i \geq 2$ have absolute values strictly less than $|\varphi_1(\alpha)|$. If $r_1 = 0$, only $\varphi_{r_2+1}(\alpha) = \varphi_1(\alpha)$ has the same absolute value as $\varphi_1(\alpha)$. But, if $\varphi_{r_2+1}(\alpha) = \varphi_1(\alpha)$, then $\varphi_1(\alpha)$ would be in $\mathbb{R}$ and hence $|\varphi_1(\alpha)| = |\text{Re}(\varphi_1(\alpha))| < 1$, which leads to a contradiction. Hence $\varphi_1(\alpha)$ is a zero of $f_{\text{char}}^\alpha$ of multiplicity 1, and from this we conclude that $m = [F : \mathbb{Q}(\alpha)] = 1$. So indeed $F = \mathbb{Q}(\alpha)$. This proves the claim and finishes the proof of the corollary.

\[\Box\]

**Exercises**

(10.A) Show that $\mathbb{Q}(\sqrt{36})$ has class group isomorphic to $\mathbb{Z}/10\mathbb{Z}$.

(10.B) Show that $\mathbb{Q}(\sqrt{-103})$ has trivial class group and the closely related fact that

\[e^{\pi \sqrt{103}} = 26253741264076874399999999999992\ldots\]

is “almost” an integer.

(10.C) Compute the structure of the class groups of $\mathbb{Q}(\sqrt{-30})$ and $\mathbb{Q}(\sqrt{-114})$.

(10.D) Show that the class group of $\mathbb{Q}(\alpha)$ where $\alpha$ is a zero of the polynomial $T^3 + T - 1$ is trivial.

(10.E) Compute the class group of $F = \mathbb{Q}(\sqrt{101})$.

(10.F) Prove the arithmetic-geometric-mean inequality: let $a_1, \ldots, a_n \in \mathbb{R}_{\geq 0}$ then

\[(a_1 \cdots a_n)^{1/n} \leq \frac{a_1 + \cdots + a_n}{n}.
\]

The equality holds if and only if $a_1 = \cdots = a_n$. (Hint: let $A = \frac{a_1 + \cdots + a_n}{n}$. Show that $e^{\frac{A^2}{n}} \geq 1$ for every i, with equality if and only if $a_i = A$.)

61
(10.G) Show that the class group of \( \mathbb{Q}(\zeta_{11}) \) is trivial.

(10.H) Let \( f(T) \in \mathbb{Z}[T] \). Show: if \( \text{Disc}(f) = 1 \), then \( f(T) = (T - k)(T - k - 1) \) for some \( k \in \mathbb{Z} \).

(10.I) Show that the ring \( \mathbb{Z}[(1 + \sqrt{19})/2] \) is not Euclidean, but admits unique factorization.

(10.J) Find all solutions \( X, Y \in \mathbb{Z} \) of the equation that we encountered in the introduction: \( Y^2 = X^3 - 19 \).

(10.K) Prove Stirling’s Formula:

\[
n! = n^n e^{-n} \sqrt{2\pi n} n^{\theta} \quad \text{for some } \theta \text{ with } 0 < \theta < 1.
\]

(10.L) Show that the Diophantine equation \( Y^2 = X^3 - 5 \) has no solutions \( X, Y \in \mathbb{Z} \). (Hint: show that the class group of \( \mathbb{Z}[\sqrt{-5}] \) has order 2.)

*(10.M) Show that for every number field \( F \) there is a prime that is ramified in \( F \) over \( \mathbb{Q} \).

*(10.N) Let \( F \) be a number field. Show that if

\[
\frac{n!}{n^n} \left( \frac{4}{\pi} \right)^{\frac{3}{2}} |\Delta_F|^{1/2} < 2
\]

then the ring of integers \( \mathcal{O}_F \) is a Euclidean for the norm \( |N(x)| \). (Hint: Let \( x \in F \otimes \mathbb{R} \). Show, using the notation of the proof of Theorem 10.3, that the set \( X(R) \cup (X(R) + x) \) with \( R = n \) has a volume which is larger than \( 2^n \text{covol} \mathcal{O}_F \). Show that it contains a lattice point.)
Chapter 11. The Theorem of Dirichlet.

In this chapter we prove Dirichlet’s famous Unit Theorem. Just as in the previous chapter, this will be done by means of Minkowski’s techniques. Dirichlet’s original proof (1863) exploited the so-called “box principle”. Note: if we speak about units in a number field $F$ then we mean elements in $O_F^*$. We introduce modified absolute values $|x|$ on $\mathbb{R}$ and $\mathbb{C}$:

$$|x| = \begin{cases} |x|, & \text{on } \mathbb{R}; \\ |x|^2, & \text{on } \mathbb{C}. \end{cases}$$

**Definition.** Let $F$ be a number field of degree $n$ with $r_1$ embeddings $\varphi_i: F \rightarrow \mathbb{R}$ and $2r_2$ remaining embeddings $\varphi_i: F \hookrightarrow \mathbb{C}$. Let the homomorphism $\Psi$ be given by:

$$\Psi: O_F^* \rightarrow \mathbb{R}^{r_1 + r_2}$$

$$\varepsilon \mapsto (\log|\varphi_1(\varepsilon)|, \ldots, \log|\varphi_{r_1+r_2}(\varepsilon)|),$$

where $\varphi_1, \ldots, \varphi_{r_1}$ denote the real embeddings and $\varphi_{r_1+1}, \ldots, \varphi_{r_1+r_2}$ denote a set of mutually non-conjugate complex embeddings.

**Theorem 11.1.** (P. Lejeune Dirichlet) Using the notation above:

(i) The kernel of $\Psi$ is finite and equal to $\mu_F$, the group of the roots of unity of $F$.

(ii) The image of $\Psi$ is a lattice in the space

$$H = \{(x_1, \ldots, x_{r_1+r_2}) \in \mathbb{R}^{r_1+r_2} | \sum x_i = 0\},$$

which is of codimension 1 in $\mathbb{R}^{r_1+r_2}$.

**Proof.** (i) Let $\zeta \in \mu_F$ be a root of unity in $F$. Then there is an integer $n \neq 0$ such that $\zeta^n = 1$. This implies that $n\Psi(\zeta) = 0$; hence $\Psi(\zeta) = 0$. This shows that the roots of unity are in the kernel. Next we show that the kernel of $\Psi$ is finite. This implies that $\ker(\Psi) = \mu_F$.

For any $\varepsilon \in \ker(\Psi)$ we have that $|\varphi(\varepsilon)| = 1$ for all embeddings $\varphi: F \rightarrow \mathbb{C}$. Viewing $O_F$ via the map $\Phi$ of Chapter 2 as a lattice inside the vector space $F \otimes \mathbb{R}$, we see that the kernel of $\Psi$ is contained in the bounded set $B$ of points $(x_1, \ldots, x_{r_1}, y_1, \ldots, y_{r_2}) \in \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$ for which

$$|x_i| \leq 1 \quad \text{for } 1 \leq i \leq r_1,$$

$$|y_i| \leq 1 \quad \text{for } 1 \leq i \leq r_2.$$  

Example 8.2 implies that $B \cap \Phi(O_F)$ is finite and therefore that $\ker(\Psi)$ is finite as required.

(ii) Let $B$ be any bounded set in $\mathbb{R}^{r_1+r_2}$. Let $B' \subset \mathbb{R}^{r_1+r_2}$ be the box

$$\{(x_1, \ldots, x_{r_1+r_2}) | |x_i| \leq R \quad \text{for } 1 \leq i \leq r_1 + r_2\},$$

where $R$ is so large that $B \subset B'$. The elements $\varepsilon \in O_F^*$ that have $\Psi(\varepsilon) \in B'$ satisfy

$$|\varphi_i(\varepsilon)| \leq \begin{cases} \exp(R), & \text{for real embeddings } \varphi_i; \\ \exp(R/2), & \text{for complex embeddings } \varphi_i. \end{cases}$$

Viewing $O_F$ via $\Phi$ as a lattice in $F \otimes \mathbb{R}$, we see that the elements $\varepsilon \in O_F^*$ that satisfy $\Psi(\varepsilon) \in B'$ are in a bounded box in $F \otimes \mathbb{R}$. Therefore there are only finitely many such $\varepsilon$ and a fortiori there are only finitely many elements in $B' \cap \Psi(O_F^*)$. We conclude that $\Psi(O_F^*)$ is discrete.
By Exercise 4.E, every unit $\varepsilon \in O_F^*$ has $N(\varepsilon) = \pm 1$. Therefore

$$1 = |N(\varepsilon)| = \prod_{\sigma:F \to \mathbb{C}} |\sigma(\varepsilon)| = \prod_{i=1}^{r_1 + r_2} \|\sigma_i(\varepsilon)\|.$$  

This easily implies that $\Psi(O_F^*)$ is contained in the subspace $H \subset \mathbb{R}^{r_1 + r_2}$.

To complete the proof, we must show that $\Psi(O_F^*)$ spans $H$. This will be done by invoking two lemmas that will be stated and proved after the proof of this theorem.

Let $1 \leq i \leq r_1 + r_2$. By Lemma 11.2 there exist non-zero integral elements $x_1, x_2, x_3, \ldots \in O_F$, such that $|N(x_i)|$ is bounded by $\sqrt{|\Delta_F|} + 1$ and

$$\|\varphi_j(x_1)\| > |\varphi_j(x_2)| > |\varphi_j(x_3)| > \cdots \quad \text{for all } j \neq i.$$  

By Prop. 6.3(iv) there are only finitely many ideals in $O_F$ with bounded norm. This implies that the collection of principal ideals $\{(x_k)\}_{k}$ is finite. Therefore there exist at least two indices $j < j'$ such that $(x_j) = (x_{j'})$. We define the unit $\varepsilon_i$ by

$$\varepsilon_i = \frac{x_{j'}}{x_j}.$$  

By construction, $\varepsilon_i$ satisfies

$$\|\varphi_j(\varepsilon_i)\| < 1 \quad \text{for all } j \neq i.$$  

Consider the matrix with entries $a_{ij} = \log|\varphi_j(\varepsilon)|$ where $1 \leq i, j \leq r_1 + r_2$. It satisfies $a_{ij} < 0$ whenever $i \neq j$ and it satisfies $\sum_j a_{ij} = 0$. Therefore Lemma 11.3 implies that any $(r_1 + r_2 - 1) \times (r_1 + r_2 - 1)$-minor is invertible. This implies that the rank of $(a_{ij})_{i,j}$ is $r_1 + r_2 - 1$ and the theorem is proved. \(\square\)

**Lemma 11.2.** Let $F$ be a number field of degree $n$. Let $\varphi_1, \ldots, \varphi_{r_1}$ denote the different homomorphisms $F \to \mathbb{R}$ and $\varphi_{r_1+1}, \ldots, \varphi_{r_1+r_2}$ the remaining, pairwise non-conjugate embeddings $F \to \mathbb{C}$. Then there exists for each index $1 \leq i \leq r_1 + r_2$ a sequence of integers $\alpha_1, \alpha_2, \alpha_3, \ldots \in O_F - \{0\}$, with $|N(\alpha_j)| \leq \sqrt{|\Delta_F|} + 1$ and

$$|\varphi_j(\alpha_1)| > |\varphi_j(\alpha_2)| > |\varphi_j(\alpha_3)| > \cdots$$

for all indices $j \neq i$.

**Proof.** Let $i$ be an index with $1 \leq i \leq r_1 + r_2$. The existence of the $\alpha_j$ is proved by applying Minkowski’s theorem to boxes that are “thin” in every direction except in the direction of the $i$-th coordinate. In this direction the box is so large that its volume is larger than $2^n \text{cvol}(O_F)$. We will contract the integers $\alpha_j \in O_F$ inductively. We take $\alpha_1 = 1$. Suppose that $\alpha_1, \ldots, \alpha_m$ have been constructed. Let $\beta_j = \frac{1}{2} |\varphi_j(\alpha_m)|$ for $j \neq i$ and let $\beta_i \in \mathbb{R}$ be defined by the relation

$$\prod_j \beta_j = \sqrt{|\Delta_F|} + 1.$$  

Consider the box

$$B = \{(x_1, \ldots, x_{r_1 + r_2}) \in \mathbb{R}^{r_1} \times \mathbb{C}^{r_2} \mid |x_j| \leq \beta_j \text{ for all } j \neq i\}.$$  

This is a bounded, symmetric and convex subset of $\mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$. It has volume

$$\text{vol}(B) = \prod_{j=1}^{r_1} (2\beta_j) \prod_{j=r_1+1}^{r_1+r_2} (\pi \beta_j) = 2^{r_1} \pi^{r_2} \left(\sqrt{|\Delta_F|} + 1\right)$$

64
which is easily seen to exceed $2^n 2^{-r_2} \sqrt{\Delta_F} = 2^n \text{vol}(O_F)$.

By Minkowski's Theorem 10.1, there is a non-zero element $x$ in $B \cap O_F$, where as usual we view $O_F$ as a lattice in the vector space $\mathbb{R}^{n_1} \times \mathbb{C}^{r_2}$ via the map $\Phi$ of Chapter 2. We take $\alpha_{m+1} = x$ and we verify that

$$|N(\alpha_{m+1})| = \prod_{j=1}^{r_1+r_2} |\varphi_j(\alpha_{m+1})| \leq \prod_{j=1}^{r_1+r_2} \beta_j = \sqrt{\Delta_F} + 1,$$

$$|\varphi_j(\alpha_{m+1})| \leq \beta_j = \frac{1}{2} |\varphi_j(\alpha_m)| < |\varphi_j(\alpha_m)|$$

This proves the lemma. \qed

**Lemma 11.3.** Let $(a_{ij})_{i,j}$ be an $m \times m$-matrix with real entries. Suppose that

$$a_{ij} < 0 \quad \text{when } i \neq j,$$

$$\sum_j a_{ij} > 0 \quad \text{for all } i.$$

Then $(a_{ij})_{i,j}$ has rank $m$.

**Proof.** Suppose that the rank of $(a_{ij})_{i,j}$ is less than $m$. Then there is a non-trivial relation $\sum_i \lambda_i a_{ij} = 0$ with not all $\lambda_i \in \mathbb{R}$ equal to zero. Suppose $\lambda_k$ has the largest absolute value of the $\lambda_i$. Since we can multiply the relation by $-1$, we may assume that $\lambda_k > 0$. We have that $\lambda_k \geq \lambda_i$ for all indices $i$. Therefore $\lambda_k a_{ik} \leq \lambda_i a_{ik}$ for all indices $i$, including $i = k$. Taking the sum over $i$, we find

$$0 < \lambda_k \sum_{i=1}^m a_{ik} = \sum_{i=1}^m \lambda_k a_{ik} \leq \sum_{i=1}^m \lambda_k a_{ik} = 0.$$

This contradiction proves the lemma. \qed

**Corollary 11.4.** Let $F$ be a number field with precisely $r_1$ distinct embeddings $F \hookrightarrow \mathbb{R}$ and $2r_2$ remaining embeddings $F \hookrightarrow \mathbb{C}$. Let $\mu_F$ be the group of roots of unity in $O_F^*$. Then

(i) There exist a set of so-called fundamental units $\varepsilon_1, \ldots, \varepsilon_{r_1+r_2-1} \in O_F^*$ such that

$$O_F^* = \{ \zeta^{n_1} \cdot \ldots \cdot \zeta^{n_{r_1+r_2-1}} \mid \zeta \in \mu_F \quad \text{and} \quad n_1, \ldots, n_{r_1+r_2-1} \in \mathbb{Z} \}.$$

(ii) There is an isomorphism of abelian groups

$$O_F^* \cong \mathbb{Z} / w_F \mathbb{Z} \times \mathbb{Z}^{r_1+r_2-1},$$

where $w_F$ denotes the number of roots of unity in $F$.

**Proof.** By Theorem 11.1(ii) we can choose $r_1 + r_2 - 1$ units $\varepsilon_i$ in $O_F^*$ such that the vectors $\Psi(\varepsilon_i)$ span the lattice $\Psi(O_F^*)$. For an arbitrary unit $u \in O_F^*$ there exist integers $n_1, \ldots, n_{r_1+r_2-1}$ such that

$$\Psi(u) = n_1 \Psi(\varepsilon_1) + \cdots + n_{r_1+r_2-1} \Psi(\varepsilon_{r_1+r_2-1}).$$

By Theorem 11.1(i) we see that $u \varepsilon^{-n_1} \cdot \ldots \cdot \varepsilon^{-n_{r_1+r_2-1}}$ is in the kernel of $\Psi$ and therefore a root of unity. This proves (i). Part (ii) follows from the fact that the roots of unity are algebraic integers and form a cyclic group. \qed

65
Definition 11.5. Let $F$ be a number field of degree $n$ and let $\varphi_1, \ldots, \varphi_{r_1+r_2}$ be the homomorphisms $F \to \mathbb{C}$ as in Definition 2.5. The regulator $R_F$ of $F$ is defined to be
\[
\left| \det \left( \log |\varphi_j(\varepsilon_i)| \right)_{i,j} \right|,
\]
where $\varepsilon_1, \ldots, \varepsilon_{r_1+r_2-1}$ are a set of fundamental units and the $\varphi_j$ run over the homomorphisms in the set $\{ \varphi_1, \ldots, \varphi_{r_1+r_2} \}$ except one.

The regulator $R_F$ of a number field $F$ is well-defined, i.e., it does not depend on the homomorphism $\varphi_i$ that one leaves out. We shall first discuss some concrete examples; after that we give another description of the regulator, from which it will be clear that it is well-defined.

Example 11.6. Consider the field $F = \mathbb{Q}(\sqrt{d})$ where $d \in \mathbb{Z}_{>0}$ We have that $r_1 = 2$ and $r_2 = 0$. It follows from Dirichlet’s Unit Theorem that the unit group $O_F^*$ is larger than $\{ \pm 1 \}$. It is easy to see that $\varepsilon = X + Y \sqrt{d} \in O_F$ for some $X, Y \in \mathbb{Z}$ if and only if $N(\varepsilon) = X^2 - dY^2 = \pm 1$. Therefore, at least when $d \equiv 2, 3 \pmod{4}$, Dirichlet’s Unit Theorem implies that the Diophantine Equation
\[
X^2 - dY^2 = \pm 1
\]
has non-trivial solutions $X, Y \in \mathbb{Z}$, i.e., solutions different from the ones with $Y = 0$. This equation is usually called Pell’s Equation. It is by no means obvious to actually find these non-trivial solutions.

For instance, when $d = 94$, the smallest solutions are $X = 2143295$ and $Y = 221064$. Equivalently, the unit group $\mathbb{Z}[\sqrt{94}]^*$ is generated by $-1$ and $\varepsilon = 2143295 + 221064 \sqrt{94}$. Hence the regulator of $\mathbb{Q}(\sqrt{94})$ equals $\log(2143295 + 221064 \sqrt{94}) \approx 15.271002$. (Note that if we set $\varepsilon' = 2143295 - 221064 \sqrt{94}$ then $\varepsilon \cdot \varepsilon' = 1$, by construction, so the logarithms of $\varepsilon$ and $\varepsilon'$ have the same absolute value.)

Example 11.7. Consider the field $F = \mathbb{Q}(\sqrt{257})$. We have $r_1 = 2$ and $r_2 = 0$. Since $F$ admits embeddings into $\mathbb{R}$, the group of roots of unity in $F$ is $\{ \pm 1 \}$. By Dirichlet’s Unit Theorem we therefore have that
\[
O_F^* \cong \mathbb{Z}^2 \times \{ \pm 1 \}.
\]
We will determine the class group $\text{Cl}(O_F)$ and the unit group of $O_F$ together. By Example 4.4, the ring of integers of $F$ is equal to $\mathbb{Z}[\alpha]$ where $\alpha = (1 + \sqrt{257})/2$. By Example 4.7, the discriminant of $F$ is 257. Minkowski’s constant for $F$ is easily calculated to be equal to
\[
\frac{2!}{2^2} \sqrt{257} \approx 8.01.
\]
The minimum polynomial of $\alpha$ is easily seen to be $f(T) = T^2 - T - 64$. We first substitute a few integers $n$ into $f$. In order to obtain small values of $f(n)$, we choose $n$ close to the zero $(1 + \sqrt{257})/2 \approx 8.5 \in \mathbb{R}$. See Table I.

Since none of the numbers $f(n)$ is divisible by 3, 5 or 7, we conclude that $f$ has no zeroes modulo 3, 5 or 7. By the Factorization Lemma 9.1, we conclude that the ideals $(3), (5)$ and $(7)$ are prime in $O_F$. Therefore, the only primes having norm less than 8.01 in $O_F$ are the prime divisors $p_2$ and $p_2'$ of 2. From the Factorization Lemma we deduce that $p_2 = (\alpha, 2)$ and $p_2' = (\alpha - 1, 2)$.

Since the classes of $p_2$ and $p_2'$ are inverse to one another in the class group, we conclude that the class group of $O_F$ is cyclic. It is generated by the class of $p_2$. From entry (iv) or (v) of the table, it is immediate that
\[
p_2^3 \sim 1
\]
Table I.

and we see that $\text{Cl}(O_F)$ is cyclic of order 3 or 1. The class group is trivial if and only if $p_2$ is principal. If $p_2$ were principal and $\gamma = a + b(1 + \sqrt{257})/2$, with $a, b \in \mathbb{Z}$ would be a generator, we would have the following equation:

$$\pm 2 = N(\gamma) = a^2 + ab - 64b^2.$$  

This Diophantine equation is not so easy to solve directly, so we proceed in a different way. We will need to know the unit group $O_F^*$ first.

From the 4th and 5th line of the table we deduce the following decomposition into prime ideals:

$$(\alpha - 8)(\alpha - 9) = p_2^3 p_2^3$$

Since we also have that $(8) = p_2^3 p_2^3$, we see that the principal ideals $((\alpha - 8)(\alpha - 9))$ and $(8)$ are equal. Therefore their generators differ by a unit $\varepsilon \in O_F$. Taking norms, we see that $N(\varepsilon) = -1$ and we conclude that $\varepsilon \neq \pm 1$. We find, in fact, that

$$\varepsilon = \frac{(\alpha - 8)(\alpha - 9)}{8} = -2\alpha + 17 = 16 - \sqrt{257}.$$  

However, it is not clear that $\varepsilon$ is a fundamental unit in the sense of Dirichlet’s Unit Theorem. It could be that there is another unit $u \in O_F^*$ such that $\varepsilon = \pm u^k$ form some $k \geq 2$. The absolute values of $|\varphi_1(\varepsilon)|$ and $|\varphi_2(\varepsilon)|$ are $32.0312\ldots$ and $0.0312\ldots$ respectively. If $\varepsilon = \pm u^k$ for $|k| \geq 2$, we would have that $|\varphi_1(u)| \leq \sqrt{32.04} \leq 5.7$ and $|\varphi_2(u)| \leq \sqrt{0.0312} \leq 0.18$.

Therefore $u$ is contained in the intersection of the lattice $\Phi(O_F) \subset F \otimes \mathbb{R} = \mathbb{R} \times \mathbb{R}$ with the box

$$\{(x_1, x_2) \in \mathbb{R}^2 \mid |x_1| \leq 5.7 \text{ and } |x_2| \leq 0.18\}.$$  

By drawing a picture it easily checked that this intersection contains only the number 0 and we conclude that $u$ cannot exist and that $\varepsilon$ and $-1$ generate the unit group $O_F^*$. Therefore, the regulator of $F$ is $|\log(\sqrt{257} - 16)| \approx 1.5055735$.

Suppose the class group $\text{Cl}(O_F)$ is trivial. Then we have that $p_2 = (\gamma)$ and by entry (iv) of the table that $\gamma^3 = u(\alpha - 8)$ for some unit $u \in O_F^*$. Here $\gamma$ is only determined up to a unit and, consequently, the unit $u$ is only determined up to a cube of a unit. Since $-1$ is a cube, we may assume that

$$\gamma^3 = \varepsilon^k (\alpha - 8) \quad \text{for some } k \in \mathbb{Z}.$$  

This implies that for every ideal $I \subset O_F$, which is prime to $p_2$, we have that

$$\alpha - 8 = \varepsilon^k \quad \text{in } (O_F/I)^*/N$$

67
where $N \subset (O_F/I)^* \subset (O_F/I)^*$ is the subgroup of cubes, i.e., $N = ((O_F/I)^*)^3$. We test this modulo the ideal $I = (5)_{p_{13}}$. Here $p_{13} = (13, \alpha - 10) = (13, \alpha + 3)$ as in the table above.

By the Chinese Remainder Theorem we have the following isomorphism of groups

$$(O_F/I)^* / ((O_F/I)^*)^3 \cong F_{13} / (F_{13}^*)^3 \times F_{25} / (F_{25}^*)^3 \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}.$$

The last isomorphism is obtained as follows. We first observe that raising to the 4th power induces an isomorphism

$$F_{13} / (F_{13}^*)^3 \cong \mu_3 = \{1, 3, 9\} \subset F_{13}$$

and then we choose an isomorphism $\mathbb{Z}/3\mathbb{Z} \cong \mu_3$, for instance by mapping $x$ to $3^x$. Similarly, raising to the power 8 gives an isomorphism

$$F_{25} / (F_{25}^*)^3 \cong \mu_3 = \{1, -\alpha, \alpha^2\} \subset F_{25}.$$

Here we used that $\alpha^2 - \alpha + 1 \equiv 0 \pmod{5}$, so that $-\alpha$ is a primitive cube root of unity. The map $x \mapsto (-\alpha)^x$ gives an isomorphism $\mu_3 \cong \mathbb{Z}/3\mathbb{Z}$.

We want to test whether the image of $\alpha - 8$ in $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ under this isomorphism is a multiple of the image of $\varepsilon = -2\alpha + 17$.

First we compute the image of $\alpha - 8$: modulo $p_{13}$ it is congruent to $-3 - 8 \equiv 2$. Raising this to the 4th power gives $16 \equiv 3$, which maps to $1 \in \mathbb{Z}/3\mathbb{Z}$ by our choice of the isomorphism. Modulo 5, we have that $\alpha - 8 \equiv 2 \in \mathbb{F}_{25} = \mathbb{F}_5(\alpha)$. To compute its 8th power, we observe that $\alpha^2 - \alpha + 1 \equiv 0 \pmod{5}$, so that $\bar{\alpha} + \alpha = 1$ and $\bar{\alpha}\alpha = 1$. Here $\bar{\alpha} = \alpha^5$ is the conjugate of $\alpha$ over $\mathbb{F}_5$. We find

$$(\alpha + 2)^8 = (\alpha + 2)(\alpha + 2)^5(\alpha + 2)^2$$

$$= (\alpha + 2)(\bar{\alpha} + 2)(\alpha^2 + 4\alpha + 4)$$

$$= (\alpha\bar{\alpha} + 2(\alpha + \bar{\alpha}) + 4)(\alpha - 1 + 4\alpha + 4)$$

$$= (1 + 2 + 4)(-1 + 4) = 1.$$

Since $1$ maps to $0 \in \mathbb{Z}/3\mathbb{Z}$, we find that the image of $\alpha - 8$ in $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ is equal to $(1_0)$.

The computation for $\varepsilon = -2\alpha + 17$ is entirely similar. We leave it to the reader. The result is that the image of $\varepsilon$ is $(1_0)$. Since this vector is not a scalar multiple of $(1_0)$, we conclude that $\alpha - 8$ is not of the form $u\gamma^3$ for any unit $u \in O_F^*$. Therefore the class group is not trivial and hence cyclic of order 3.

We close this chapter by giving another description of the regulator. Let $F$ be a number field of degree $n$. In Chapter 2 we have defined the map $\Phi : F \to F \otimes \mathbb{R}$, and we have seen that it realizes the ring of integers $O_F$ as a lattice in $F \otimes \mathbb{R} \cong \mathbb{R}^n$. If we provide $\mathbb{R}^n$ with the usual inner product then we have seen in Prop. 8.6 that the covolume of $O_F$ equals $2^{-n^2} \cdot |\Delta_F|^{1/2}$. So we get a direct relation between $O_F$ viewed as a lattice and the discriminant $\Delta_F$.

Earlier in this chapter we have seen that the map $\Psi$ gives an embedding of $O_F^*/\mu_F$ as a lattice in the hyperplane $H \subset \mathbb{R}^{n_1+n_2}$. On $H$ we consider the inner product induced by the standard inner product on $\mathbb{R}^{n_1+n_2}$. Then it seems natural to ask whether the covolume of this lattice has any significance. The following proposition shows that, up to a factor, this covolume is precisely the regulator.

68
Proposition 11.8. The covolume of $\Psi(O_F^*)$ in the hyperplane

$$H = \{(x_1, \ldots, x_{r_1+r_2}) \in \mathbb{R}^{n+r_2} \mid \sum x_i = 0\}$$

equals $\sqrt{r_1 + r_2} \cdot R_F$. In particular, the regulator $R_F$ does not depend on the homomorphism $\varphi_j$ that one leaves out in Def. 11.5.

**Proof.** Write $t = r_1 + r_2$. As usual, let $\varphi_1, \ldots, \varphi_{r_1}$ be the real embeddings $F \hookrightarrow \mathbb{R}$ and let $\varphi_{r_1+1}, \ldots, \varphi_{r_1+r_2}$ be a collection of mutually non-conjugate complex embeddings. Let $\varepsilon_1, \ldots, \varepsilon_{t-1}$ be a collection of fundamental units.

Consider the vector $\xi = t^{-1/2} \cdot (1, 1, \ldots, 1) \in \mathbb{R}^t$. It is a vector of length 1, perpendicular to the hyperplane $H$. Hence the covolume of the lattice $\Psi(\mathcal{O}_F^*)$ in $H$ equals the covolume of the lattice spanned by the vectors $\xi, \Psi(\varepsilon_1), \ldots, \Psi(\varepsilon_{t-1})$ in $\mathbb{R}^t$. By Lemma 8.5(ii) this covolume equals the absolute value of the determinant of the matrix

$$\begin{pmatrix}
t^{-1/2} & \varphi_1(\varepsilon_1) & \cdots & \varphi_1(\varepsilon_{t-1}) \\
t^{-1/2} & \varphi_2(\varepsilon_1) & \cdots & \varphi_2(\varepsilon_{t-1}) \\
& \ddots & \ddots & \ddots \\
t^{-1/2} & \varphi_{t}(\varepsilon_1) & \cdots & \varphi_t(\varepsilon_{t-1})
\end{pmatrix}$$

In Def. 11.5 of the regulator $R_F$, let us choose $\varphi_j$ to be the embedding that is omitted. Now consider row number $j$ of the above matrix. Add each of the remaining rows to it; this does not change the determinant. Since $\sum_{i=1}^t \varphi_i(\varepsilon_k) = 0$ for every $k$ the resulting matrix has the form

$$\begin{pmatrix}
t^{-1/2} & \varphi_1(\varepsilon_1) & \cdots & \varphi_1(\varepsilon_{t-1}) \\
& \ddots & \ddots & \ddots \\
& \ddots & \ddots & \ddots \\
t^{-1/2} & \varphi_{t}(\varepsilon_1) & \cdots & \varphi_t(\varepsilon_{t-1})
\end{pmatrix}$$

and we readily find that the absolute value of its discriminant equals $t^{1/2} \cdot R_F = \sqrt{r_1 + r_2} \cdot R_F$. \hfill \Box

In some sense the factor $2^{-r_2}$ that appears in Prop. 8.6(i) and the factor $\sqrt{r_1 + r_2}$ that appears in the above are “experimental errors”. The problem is that we have made a fairly ad hoc choice for the measure on the vector space $\mathbb{R}^n$ (resp. on $H \subset \mathbb{R}^{n+r_2}$). There is a more canonical choice of metrics for which the covolume of $\mathcal{O}_F$ in $\mathbb{R}^n$ would come out to be exactly $|\Delta_F|^{1/2}$ and for which the covolume of $\mathcal{O}_F^*/\mu_F$ in $H$ comes out to be exactly $R_F$. We shall not go into this here.

**Exercises**

(11.A) Show that the unit group of the ring of integers of $\mathbb{Q}(\sqrt{3})$ is generated by the “golden ratio” $(1 + \sqrt{3})/2$.

(11.B) Compute the units of $\mathbb{Q}(\sqrt{229})$ and of $\mathbb{Q}(\sqrt{19})$.

(11.C) Show that if the rank of the unit group $\mathcal{U}_F^*$ of a number field $F$ is 1, then $[F : \mathbb{Q}] = 2, 3$ or 4.

(11.D) (Pell’s equation.) Show that for every positive integer $d$ the equation

$$X^2 - dY^2 = 1$$

is
has solutions $X, Y \in \mathbb{Z}_{>0}$.

(11.E) Let $f(T) \in \mathbb{Z}[T]$ be a monic polynomial all of whose roots in $\mathbb{C}$ are on the unit circle. Show that all roots of $f$ are roots of unity.

(11.F) Let $\eta \in \mathbb{C}$ be a sum of roots of unity. Show that if $|\eta| = 1$, then $\eta$ is a root of unity.

(11.G) Show that $\mathbb{Q}(\sqrt{2})^*$ and $\mathbb{Q}(\sqrt[3]{2})^*$ are isomorphic abelian groups.
Chapter 12. Examples.

In this chapter we illustrate the theory of the preceding chapters by means of three elaborate examples.

Example 12.1. Let \( g(T) \in \mathbb{Z}[T] \) be the polynomial

\[
g(T) = T^3 + T^2 + 5T - 16.
\]

It is easily checked that \( g \) has no zeroes in \( \mathbb{Z} \). By Gauss’s lemma it is therefore irreducible in \( \mathbb{Q}[T] \). Let \( F \) be the field \( \mathbb{Q}[T]/(g(T)) \) or, equivalently, let \( F = \mathbb{Q}(\alpha) \) where \( \alpha \) denotes a zero of \( g(T) \). We will calculate the ideal class group of the ring of integers of \( F \).

As we will see below, most of our information about the arithmetic of \( F \) will be deduced from the values of \( g \) at the first few small integers. Therefore we begin our calculation by computing a table of the values \( g(k) \) at the integers \( k \) with \(-10 \leq k \leq 9\). The contents of the last column will be explained below.

<table>
<thead>
<tr>
<th>( k )</th>

</tbody>
</table>

For instance, the fact that none of the values \( g(0), g(1), g(2), \ldots, g(10) \) is divisible by 11 implies that \( g \) has no zeroes modulo 11. Therefore it is irreducible in \( \mathbb{F}_{11}[T] \) and we have another proof that \( g \) is irreducible in \( \mathbb{Q}[T] \).

Next we determine the discriminant of \( F \). By Exercise 3.H the discriminant \( \Delta(1, \alpha, \alpha^2) \) can be computed in terms of the sums \( p_i \) of the \( i \)th powers of the roots of \( g \). Using Newton’s relations (Exercise 3.I), these can be expressed in terms of the symmetric polynomials \( s_1 = -1 \), \( s_2 = 5 \) and \( s_3 = 16 \) in the roots of \( g(T) \). We have

\[
p_0 = 3,
\]
\[
p_1 = s_1 = -1,
\]
\[
p_2 = -2s_2 + p_1s_1 = -2 \cdot 5 + (-1) \cdot (-1) = -9,
\]
\[
p_3 = 3s_3 + p_2s_1 - p_1s_2 = 3 \cdot 16 + (-9) \cdot (-1) - (-1) \cdot 5 = 62,
\]
\[
p_4 = -4s_4 + p_3s_1 - p_2s_2 + p_1s_3 = -4 \cdot 0 + 62 \cdot (-1) - (-9) \cdot 5 + (-1) \cdot 16 = -33.
\]

This gives us

\[
\Delta(1, \alpha, \alpha^2) = \det \begin{pmatrix} 3 & -1 & -9 \\ -1 & -9 & 62 \\ -9 & 62 & -33 \end{pmatrix} = -8763 = -3 \cdot 23 \cdot 317.
\]
Since 8763 is squarefree, the discriminant $\Delta_F$ is, by Prop. 4.8, equal to $-8763$, and the ring of integers $O_F$ is equal to $\mathbb{Z}[\alpha]$.

It is easily verified that the polynomial $g(T)$ has precisely one zero in $\mathbb{R}$. Therefore $r_1 = 1$ and $r_2 = 1$. We conclude that Minkowski’s constant is equal to

$$\frac{3!}{3^3} \sqrt{8763} = 26.4864 \ldots$$

This implies that the class group of $O_F$ is generated by the classes of the prime ideals of norm less than or equal to 26. By Prop. 6.4, the prime ideals of $O_F$ all occur in the factorization of the principal ideals $(p)$ of $O_F$, where $p$ is an ordinary prime number.

With the aid of the values of the polynomial $g(T)$ at the first few integers, given in Table I above, we easily find the zeroes of $g$ modulo $p$ for the first few prime numbers $p$. As $g$ has degree 3, this gives us the factorization of $g(T)$ modulo $p$. Using the Factorization Lemma 9.1, it is then easy to obtain the factorizations of the ideals $(p)$ in the ring $O_F$:

**Table II.**

<table>
<thead>
<tr>
<th>$p$</th>
<th>$(p)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>$p_2p_4$</td>

</tr>
</tbody>
</table>

Now we explain the contents of the third column of Table I. For $k \in \mathbb{Z}$ one has that $g(k) = N(k - \alpha)$ and hence that $|g(k)|$ is the norm of the principal ideal $(k - \alpha)$. Using these norms and the explicit descriptions of the prime ideals of $O_F$, given in Table II, it is easy to find the factorization of the principal ideals $(k - \alpha)$.

For instance, since $g(4) = 84 = 2^2 \cdot 3 \cdot 7$, the principal ideal $(\alpha - 4)$ is only divisible by prime ideals with norm 2, 3, 4 or 7. It remains to decide which prime ideals actually occur. Since, by Table II, we have $\alpha - 4 \in p_2$ but $\alpha - 4 \not\in p_4$ we see that $p_2$ divides $\alpha - 4$, but $p_4$ does not. Similarly, $p_3$ does not divide $\alpha - 4$, but $p_3^2$ does. Finally, the only prime of norm 7 that contains $\alpha - 4$ is $p_7^2$.

We conclude that the factorization of $(\alpha - 4)$ is given by

$$(\alpha - 4) = p_2^3p_2^3p_7^2.$$  

As we have seen above, the class group is generated by the classes of the prime ideals of norm $\leq 26$. Using the relations that are implied by the factorizations of the principal ideals $(\alpha - k)$, we can reduce the number of generators of the class group. For example, entry (xx) tells us that

$$p_{23}^2 \sim (p_2p_3p_7^2)^{-1},$$

i.e., the ideals $p_{23}^2$ and $(p_2p_3p_7^2)^{-1}$ belong to the same ideal class. This implies that the class of $p_{23}^2$ is in the group generated by the classes of $p_2$, $p_3$, and $p_7^2$. Similarly, entry (xvii) says that

$$p_{23} \sim (p_3p_5)^{-1}.$$
We conclude that the class group is already generated by the classes of the prime ideals dividing the primes \( p \leq 19 \). Continuing in this way, we can eliminate many of the generators, each time expressing the class of a prime ideal as a product of classes of primes of smaller norm.

By entry (vi), we eliminate \( p_{19} \); by means of the entries (iii), (iv) and (xi) we eliminate the primes over 7. Entry (xii) implies that \( p_5 \) can be missed as a generator. Since \( p_{25} \sim p_5^{-1} \), we see that \( p_{25} \) can be missed as well. The prime \( p_3 \) is taken care of by the relation implied by entry (ii). Since \( p_3' \sim p_3^{-2} \) we don’t need the prime \( p_3' \) either. Finally \( p_4 \sim p_2^{-1} \).

We conclude that the class group of \( O_F \) is generated by the class of the prime \( p_2 \). Entry (i) implies that

\[
p_2^1 \sim (1).
\]

This shows that the class group is a quotient of \( \mathbb{Z}/4\mathbb{Z} \).

Further attempts turn out not to give any new relations. This leads us to believe that the class group is perhaps isomorphic to \( \mathbb{Z}/4\mathbb{Z} \). To prove this, it suffices to show that the ideal \( p_2^2 \) is not principal. Since, by entry (ii) we have that \( p_3' \sim p_3^{-2} \sim p_2^2 \), this is equivalent to showing that the ideal \( p_3' \) is not principal.

Suppose \( p_3 = (\gamma) \) for some \( \gamma \in O_F \). By entry (ii) of Table I, we would have that \( (\gamma)^2 = (\alpha - 1) \).

Therefore

\[
\gamma^2 \cdot u = \alpha - 1 \quad \text{for some unit } u \in O_F^*.
\]

In order to show that this cannot happen, we need to know the unit group \( O_F^* \), or, at least, the units modulo squares. By Dirichlet’s Unit Theorem, the unit group has rank \( r_1 + r_2 - 1 \). Since \( F \) admits an embedding into \( \mathbb{R} \), the only roots of unity in \( F \) are \( \pm 1 \). Therefore

\[
O_F^* = \{ \pm \varepsilon^k \}_{k \in \mathbb{Z}}
\]

for some unit \( \varepsilon \in O_F^* \).

To find a unit different from \( \pm 1 \), we exploit the redundancy in the relations implied by Table I. Consider the principal ideals generated by \( (\alpha - 1)(\alpha - 2)^4 \) and \( 9\alpha \). Entries (i), (ii) and (iii) of the table imply that both these ideals factor as

\[
p_2^4 p_3^4 p_3'^2.
\]

Therefore \( ((\alpha - 1)(\alpha - 2)^4) = (9\alpha) \) and

\[
\varepsilon = \frac{(\alpha - 1)(\alpha - 2)^4}{9\alpha} = 4\alpha^2 + \alpha - 13
\]

is a unit. (In fact, its multiplicative inverse is equal to \( 129\alpha^2 + 346\alpha + 1227 \), but we won’t use this.)

Consider the images of \( \varepsilon \) and \( -1 \) under the following homomorphism:

\[
O_F^*/(O_F^*)^2 \longrightarrow (O_F/p_3)^* \times (O_F/p_7)^*/((O_F/p_7)^*)^2 \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}
\]

\[
\varepsilon \quad \mapsto \quad (-1, 4) \quad \mapsto \quad (1, 0)
\]

\[
-1 \quad \mapsto \quad (-1, -1) \quad \mapsto \quad (1, 1)
\]

Since the vectors \( \left( \begin{array}{c} 1 \\ 0 \end{array} \right) \) and \( \left( \begin{array}{c} 1 \\ 1 \end{array} \right) \) are independent, we conclude that \( \varepsilon \) and \( -1 \) generate the unit group \( O_F^* \) modulo squares. Therefore the unit \( u \) is, modulo squares, of the form

\[
u = \pm \varepsilon^k
\]

73
for some \( k \in \mathbb{Z} \). The equation satisfied by \( \alpha \) now becomes
\[
\pm \varepsilon^k \cdot \gamma^2 = \alpha - 1 \quad \text{for some } \gamma \in O_F \text{ and } k \in \mathbb{Z}.
\]
Consider this equation modulo \( p_5 \). More precisely, consider the image in the following group of order 2:
\[
(O_F^*/p_5)^* / ((O_F^*/p_5)^*)^2.
\]
Since \(-1\) is a square mod 5 and since \( \varepsilon \equiv 4 \cdot (-2)^2 - 2 - 13 \equiv 1 \) is square modulo \( p_5 \) as well, the left hand side of this equation is trivial. The right hand side, however, is congruent to \(-2 - 1 \equiv 2\) which is not a square.

We conclude that the equation has no solutions and hence that the ideal class group is cyclic of order 4.

**Example 12.3. (The Number Field Sieve)** Let \( F = \mathbb{Q}(\sqrt{2}) \). This number field \( \mathbb{Q}(\sqrt{2}) \) and its ring of integers have been exploited to factor the 9th Fermat number \( 2^{512} + 1 \) into prime factors. See [38]. The discriminant of the minimum polynomial \( T^5 - 2 \) of \( \sqrt{2} \) is easily seen to be equal to \( 50000 = 2^45^5 \). Since \( T^5 - 2 \) is an Eisenstein polynomial for the prime 2 and \( (T + 2)^5 - 2 \) is Eisenstein for 5, we conclude from Prop. 9.3 that \( \mathbb{Z}[\sqrt{2}] \) is the ring of integers of \( F \).

Since the roots of \( T^5 - 2 \) differ by 5th roots of unity, there is only one embedding \( F \ni \mathbb{R} \). Therefore \( r_1 = 1 \) and \( r_2 = 2 \). Minkowski’s constant is equal to
\[
\frac{5!}{5^5} \left( \frac{4}{\pi} \right)^2 \sqrt{50000} = 13.919 \ldots .
\]
By Cor. 10.4(iii), the class group of \( F \) is generated by the ideal classes of the primes of norm less than 13.919. We use the Factorization Lemma 9.1 to determine those primes: we already observed that \( T^5 - 2 \) and \( (T - 2)^5 - 2 \) are Eisenstein polynomials with respect to the primes 2 and 5 respectively. We conclude that both 2 and 5 are totally ramified in \( F \) over \( \mathbb{Q} \):
\[
(2) = p_2^5 \quad \text{and} \quad (5) = p_5^5.
\]
To find the prime ideals of small norm, we study the decomposition of the other primes \( p \) in \( F \). This can be done in as in Example 12.1, but here we proceed differently. Consider the map \( \mathbb{F}_p^* \rightarrow \mathbb{F}_p^* \) given by \( x \mapsto x^5 \). If \( p \not\equiv 1 \pmod{5} \), this is a bijection. This implies that in this case the polynomial \( T^5 - 2 \) has precisely one zero in \( \mathbb{F}_p \). In fact,
\[
(p) = \begin{cases} 
p_p p_p^5, & \text{if } p \equiv -1 \pmod{5}. \\
p_p p_p^5, & \text{if } p \equiv 2, 3 \pmod{5}.
\end{cases}
\]
Here \( p_p^k \) denotes a prime ideal of norm \( p^k \).

If \( p \equiv 1 \pmod{5} \), the map \( x \mapsto x^5 \) is not bijective. If 2 is a 5th power in \( \mathbb{F}_p^* \), then \( T^5 - 2 \) decomposes as a product of linear factors modulo \( p \). If not, \( T^5 - 2 \) is irreducible. For instance, \( T^5 - 2 \) is irreducible mod 11.

We conclude that for \( p = 2, 3, 5, 7 \) and 13 there is precisely one prime ideal \( (p_2, p_3, p_5, p_7 \) and \( p_{13}, \) respectively) of norm \( p \). These are all the prime ideals of norm less than 13.919. They generate the class group. In order to determine the structure of the class group, we factor some elements of small norm.
Table III.

<td>$p_5 p_{13}$</td>
</tr>
</tbody>
</table>

By relation (viii), the ideal $p_{13} p_5$ is principal. This implies that

$$p_{13} \sim p_5^{-1}$$

i.e., the ideal class of $p_{13}$ is equal to the class of $p_5^{-1}$. Therefore, the ideal class group of $F$ is already generated by the classes of $p_2$, $p_3$, $p_5$ and $p_7$. In a similar way, by considering the relations (vii) and (iv), we see that Cl($\mathcal{O}_F$) is, in fact, generated by $p_2$ and $p_3$. But both these ideals are principal: it follows from entries (i) and (iii) that they are generated by $\alpha$ and $\alpha + 1$ respectively. We conclude that the class group of $\mathcal{O}_F$ is trivial.

By Dirichlet's Unit Theorem the unit group $\mathcal{O}_F^*$ has rank $r_1 + r_2 - 1 = 1 + 2 - 1 = 2$. From the table we obtain one unit $\alpha - 1 = \sqrt[5]{2} - 1$. It does not seem easy to obtain independent units with small absolute values by extending the table further. Therefore we search, by brute force, among elements of the form $x = a + b\alpha + c\alpha^2$ with $a, b, c \in \mathbb{Z}$. By Prop. 3.2(iii) one has that

$$N(x) = \left(a + b\sqrt[5]{2} + c\sqrt[4]{4}\right)\left|a + b\sqrt[5]{2}e^{\frac{2\pi i}{5}} + c\sqrt[4]{4}e^{\frac{2\pi i}{3}}\right|^2 = \left|a + b\sqrt[5]{2}e^{\frac{2\pi i}{5}} + c\sqrt[4]{4}e^{\frac{2\pi i}{3}}\right|^2.$$ 

Calculating a few values of $N(a + b\alpha + c\alpha^2)$ with $|a|, |b|, |c| \leq 1$, one finds that $N(1 - \alpha + \alpha^2) = -3$. It follows from the table that

$$\frac{1 - \alpha + \alpha^2}{\alpha + 1} = \alpha^4 - \alpha^3 + \alpha^2 - 1$$

is a unit.

**Example 12.4.** Consider the following (randomly selected, Trento, december 1990) polynomial

$$f(T) = T^4 - 2T^2 + 3T - 7 \in \mathbb{Z}[T].$$

This polynomial is irreducible modulo 2. This follows from the fact that it is an Artin-Schreier polynomial, but it can also easily be checked directly. We will study the number field $F = \mathbb{Q}(\alpha)$, where $\alpha$ is a zero of $f(T)$.

First of all we substitute all integers $n$ with $-18 \leq n \leq 18$ in $f(T)$ and factor the result as a product of prime numbers:
To evaluate the discriminant of \( f(T) \), we compute the sums \( p_i \) of the \( i \)-th powers of its roots in \( \mathbb{C} \) using Newton’s relations (Exercise 3.1):

\[
p_1 = 0
\]
\[
p_2 = -2s_2 + p_1s_1 = -2 \cdot 2 + 0 = 4
\]
\[
p_3 = 3s_3 + p_2s_1 - p_1s_2 = 3 \cdot (-3) + 0 + 0 = -9
\]
\[
p_4 = 2p_2 - 3p_1 + 7p_0 = 2 \cdot 4 - 0 + 7 \cdot 4 = 36
\]
\[
p_5 = 2p_3 - 3p_2 + 7p_1 = 2 \cdot (-9) - 3 \cdot 4 + 0 = -30
\]
\[
p_6 = 2p_4 - 3p_3 + 7p_2 = 2 \cdot 36 - 3 \cdot (-9) + 7 \cdot 4 = 127
\]

We have that

\[
\text{Disc}(f) = \det \begin{pmatrix} 4 & 0 & 4 & -9 \\ 0 & 4 & -9 & 36 \\ 4 & -9 & 36 & -30 \\ -9 & 36 & -30 & 127 \end{pmatrix} = -98443
\]

which is a prime number. We conclude from Prop. 4.8 that \( \Delta_F = -98443 \) and that \( O_F = \mathbb{Z}[\alpha] \).
From Exercise 4.6 we deduce that \( (-1)^{r_2} = -1 \) and we conclude that \( r_2 = 1 \) and hence that \( r_1 = 2 \). Minkowski’s constant is equal to

\[
\frac{4!}{4^4} 
\sqrt{98443} = 37.45189 \ldots
\]

By Minkowski’s Theorem, the ideal class group \( \text{Cl}(O_F) \) is generated by the primes of norm less than 37.4511. . . . In order to calculate the class group, we determine the primes of small norm first.

We see in Table IV that the polynomial \( f(T) \) has no zeroes modulo \( p \) for the primes \( p = 2, 3, 17, 23 \) and 29. We leave it to the reader to verify that \( f(T) \) has no zeroes modulo 37 either. By the Factorization Lemma we conclude that there are no prime ideals of norm \( p \) for these primes \( p \). It is easily checked that \( f(T) \) is irreducible modulo 2 and 3 and that \( f(T) \equiv (T - 1)(T + 2)(T^2 - T + 1) \pmod{5} \). The polynomial \( T^2 - T + 1 \) is irreducible modulo 5.
This gives us the following list of all prime ideals of norm less than 37.45\ldots: the ideals (2) and (3) are prime and (5) = \(p_5p'_5p_{25}\), where \(p_5\) and \(p'_5\) have norm 5 and \(p_{25}\) is a prime of norm 25. The other primes \(p_p\) and \(p'_p\) of norm less 37.45\ldots have prime norm \(p\). They are listed in Table V and are easily computed from Table IV.

**Table V.**

| \(p_5\) = \((5, \alpha - 1)\) | \(p_5' = (5, \alpha + 2)\) |
| \(p_7\) = \((7, \alpha)\) | \(p_7' = (7, \alpha - 2)\) |
| \(p_{11}\) = \((11, \alpha + 1)\) | \(p_{11}' = (11, \alpha - 5)\) |
| \(p_{13}\) = \((13, \alpha - 3)\) | \(p_{13}' = (13, \alpha - 6)\) |
| \(p_{19}\) = \((19, \alpha - 6)\) | \(p_{19}' = (19, \alpha + 9)\) |
| \(p_{31}\) = \((31, \alpha + 8)\) | \(p_{31}' = (31, \alpha + 14)\) |

The class group is generated by the classes of these primes and the class of \(p_{25}\). There exist, however, many relations between these classes. In the following table we list the factorizations of some numbers of the form \(q - pa\), where \(p, q \in \mathbb{Z}\). We have chosen numbers of this form because \(N(q - pa) = p^4f(q/p)\) can be computed so easily. The factorizations into prime ideals of the principal ideals \((q - pa)\) give rise to relations in the class group. For instance \(N(1 - 4\alpha) = -2015 = -5 \cdot 13 \cdot 31\) and \((1 - 4\alpha) = p_5p_{13}p_{31}\). This shows that the ideal class of \(p_5p_{13}p_{31}\) is trivial. Therefore the class of \(p_{31}\) can be expressed in terms of classes of prime ideals of smaller norm:

\[
p_{31} \sim p_{5}^{-1}p_{13}^{-1}.
\]

We conclude that the ideal \(p_{31}\) is not needed to generate the ideal class group. In a similar way one deduces from Table VI below that the ideal classes of the primes of norm 31, 19, 13 and 11 can all be expressed in terms of ideal classes of primes of smaller norm.

**Table VI.**

| \(\beta\) | \(N(\beta)\) | \((\beta)\) |
| \((i)\) | \(4\alpha + 1\) | \(-5 \cdot 31 \cdot 13\) | \(p_5p_{13}p_{31}\) |
| \((ii)\) | \(3\alpha - 2\) | \(-31\) | \(p_{31}'\) |
| \((iii)\) | \(\alpha - 6\) | \(5 \cdot 13 \cdot 19\) | \(p_{5}p_{13}'p_{19}\) |
| \((iv)\) | \(2\alpha - 1\) | \(-5 \cdot 19\) | \(p_{31}'\) |
| \((v)\) | \(\alpha + 7\) | \(5^2 \cdot 7 \cdot 13\) | \(p_{5}^{-2}p_{13}'\) |
| \((vi)\) | \(3\alpha - 5\) | \(13\) | \(p_{13}'\) |
| \((vii)\) | \(\alpha - 3\) | \(-5 \cdot 13\) | \(p_{5}p_{13}\) |
| \((viii)\) | \(\alpha + 1\) | \(-11\) | \(p_{11}\) |
| \((ix)\) | \(3\alpha - 4\) | \(5^2 \cdot 11\) | \(p_{5}^{-2}p_{11}'\) |

We conclude that \(\text{Cl}(O_F)\) is generated by the primes \(p_5, p'_5, p_7, p'_7\) and \(p_{25}\). One does not need entry (vi) to conclude this, but this entry will be useful later.

The primes of norm 5 and 7 are all principal. This follows form the first few lines of Table I. Finally, since \(p_5p'_5p_{25} = (5)\), one concludes that \(p_{25}\) is principal. We have proved that the class group of \(\mathbb{Q}(\alpha)\) is trivial.

By Dirichlet’s Unit Theorem, the unit group has rank \(r_1 + r_2 - 1 = 2 + 1 - 1 = 2\). The group of roots of unity is just \(\{\pm 1\}\). In all our calculations, we have not encountered a single unit yet! To find units, it is convenient to calculate the norms of some elements of the form \(a + b\alpha + c\alpha^2\) with
\(a, b, c \in \mathbb{Z}\). This can be done as follows: one calculates approximations of the roots \(\alpha_1, \alpha_2, \alpha_3, \overline{\alpha_3}\) of \(f\) in \(\mathbb{C}\):

\[
\begin{align*}
\alpha_1 &= -2.195251731 \ldots \\
\alpha_2 &= 1.655743097 \ldots \\
\alpha_3 &= .269754317 \ldots \pm 1.361277001 \ldots i
\end{align*}
\]

By Prop. 2.7(iii) one has that

\[
N(a + b\alpha + c\alpha^2) = (a + b\alpha_1 + c\alpha_1^2) (a + b\alpha_2 + c\alpha_2^2) |a + b\alpha_3 + c\alpha_3^2|^2.
\]

Calculating norms of some small elements of the form \(a + b\alpha + c\alpha^2\) one soon finds that \(N(1 + \alpha - \alpha^2) = 5\). This shows that the ideals \(1 + \alpha - \alpha^2\) and \(p_5'\) are equal. In Table IV, we read that \(p_5' = (\alpha + 2)\).

We conclude that

\[
\varepsilon_1 = \frac{1 + \alpha - \alpha^2}{\alpha + 2} = \alpha^3 - 2\alpha^2 + 3\alpha - 4
\]

is a unit. Similarly one finds that \(N(2 - 2\alpha + \alpha^2) = 65\). One easily checks that \(2 - 2\alpha + \alpha^2 = p_5'p_{13}'\).

In Table VI(vi) we see that \(p_{13}' = (3\alpha - 5)\). We conclude that the principal ideals \(2 - 2\alpha + \alpha^2\) and \((\alpha + 2)(3\alpha - 5)\) are equal. This implies that

\[
\varepsilon_2 = \frac{2 - 2\alpha + \alpha^2}{(3\alpha - 5)(\alpha + 2)} = \alpha^3 + \alpha^2 + \alpha + 3
\]

is a unit.

Rather than proving that the units \(\varepsilon_1, \varepsilon_2\) and \(-1\) generate the unit group, we merely provide some evidence for this. We use the main results of the next chapter. We use the \(\zeta\)-function of the field \(F\). Theorem 13.4 gives us an expression for the residue of the Dedekind \(\zeta\)-function \(\zeta_F(s)\) associated to \(F\) at \(s = 1\). Since the Riemann \(\zeta\)-function \(\zeta_Q(s)\) has a residue equal to 1 at \(s = 1\), one can express the content of Theorem 13.4 as follows

\[
\lim_{s \to 1} \frac{\zeta_F(s)}{\zeta_Q(s)} = \frac{2^{r_1}(2\pi)^{r_2} h_F R_F}{w_F \sqrt{|\Delta|}}.
\]

Using the Euler product formula for the \(\zeta\)-functions and ignoring problems of convergence this gives rise to

\[
\prod_p \frac{\prod_{p \mid \sigma} \left(1 - \frac{1}{N(p)}\right)^{-1}}{(1 - \frac{1}{p})^{r_1}} = \frac{2^{r_1}(2\pi)^{r_2} h_F R_F}{w_F \sqrt{|\Delta|}}.
\]

We know most factors in the right hand side: \(r_1 = 2, r_2 = 1, w_F = 2\) and \(\Delta = -98443\). By the calculation above we have that \(h_F = 1\).

Next we calculate more explicitly the factors in the Euler product on the left hand side. For a given prime \(p\), the factor is

\[
\prod_{p \mid \sigma} \left(1 - \frac{1}{N(p)}\right)^{-1}.
\]

To determine it, we must find the way the prime \(p\) splits in the extension \(\mathbb{Q} \subset F\). Apart from the ramified prime 98443, there are five possibilities. Using the Factorization Lemma they can be
distinguished by the factorization of \( f(T) \in \mathbb{F}_p [T] \):

\[
(p) = \begin{cases} 
(i) & p \mid p, p'_{p_p}, p''_{p_p}, \text{ if } f(T) \text{ has 4 zeroes mod } p, \\
(ii) & p \mid p_1, p_2, \text{ if } f(T) \text{ has exactly } 2 \text{ zeroes mod } p, \\
(iii) & p \mid p_2, \text{ if } f(T) \text{ has only one zero mod } p, \\
(iv) & p \mid p_1', \text{ if } f(T) \text{ has two irreducible quadratic factors mod } p, \\
(v) & \text{if } f(T) \text{ is irreducible mod } p.
\end{cases}
\]

Here \( p, p_1, \) etc. denote primes of norm \( p, p^2 \) etc. We find that

\[
\prod_p F(p)^{-1} = \frac{4\pi}{\sqrt{98443}} R_F
\]

where

\[
F(p) = \left( 1 - \frac{1}{p} \right)^3 \quad \text{in case (i),}
\]

\[
= \left( 1 - \frac{1}{p} \right) \left( 1 - \frac{1}{p^2} \right) \quad \text{in case (ii),}
\]

\[
= \left( 1 - \frac{1}{p^3} \right) \quad \text{in case (iii),}
\]

\[
= \left( 1 + \frac{1}{p} \right) \left( 1 - \frac{1}{p^2} \right) \quad \text{in case (iv),}
\]

\[
= \left( 1 + \frac{1}{p} + \frac{1}{p^2} + \frac{1}{p^3} \right) \quad \text{in case (v).}
\]

If we assume that the units \( \varepsilon_1, \varepsilon_2 \) are fundamental, we can compute the regulator using the two real embeddings \( \varphi_1, \varphi_2 : F \hookrightarrow \mathbb{R} \) given by \( \alpha \mapsto \alpha_1 \) and \( \alpha \mapsto \alpha_2 \) respectively. This gives

\[
R_F = \det \begin{pmatrix} \log |\varphi_1(\varepsilon_1)| & \log |\varphi_1(\varepsilon_2)| \\ \log |\varphi_2(\varepsilon_1)| & \log |\varphi_2(\varepsilon_2)| \end{pmatrix} \approx \det \begin{pmatrix} 3.427619209 & 1.600462837 \\ -3.752710586 & 2.47954524 \end{pmatrix} \approx 14.50597965.
\]

So, assuming that the units \( \varepsilon_1, \varepsilon_2 \) are fundamental we find that the right hand side of the equation is equal to

\[
\frac{4\pi}{\sqrt{98443}} \cdot 14.50597965 \approx 0.5809524077.
\]

If the units are not fundamental, the regulator is \( k \) times as small, for some positive integer \( k \). This would imply that the value 0.5809524077 is replaced by 0.2904762039 or 0.1936508026 or \ldots etc.

We compute the left hand side by simply evaluating the contribution of the primes less than a certain moderately large number. A short computer program enables one to evaluate this product with some precision. It suffices to count the zeroes of \( f(T) \) modulo \( p \). To distinguish between cases (iv) and (v) one observes that in case (iv), the discriminant of \( f(T) \) is a square modulo \( p \), while in case (v) it isn’t. See Exercises 12.C and 12.D.

Using the primes less than 1657 one finds 0.5815983 for the value of the Euler product. This is close to the number 0.5809524077 that we found above. In view of the slow convergence of the Euler product, the error is not unusually large. It is rather unlikely that the final value will be two times, three times or even more times as small. This indicates, but does not prove, that the units \( \varepsilon_1 \) and \( \varepsilon_2 \) are indeed fundamental. To prove that they are fundamental, one should employ different techniques, related to methods to search for short vectors in lattices.
Exercises

(12.A) Pick integers $A, B, C, D \in \mathbb{Z}$, satisfying $|A|, |B|, |C|, |D| \leq 4$ until the polynomial $f(T) = T^4 + AT^3 + BT^2 + CT + D$ is irreducible. Let $\alpha$ denote a zero of $F(T)$. Determine the class group of $\mathbb{Q}(\alpha)$.

(12.B) Determine which of the prime ideals in table IV are in which of the four ideal classes of $O_F$ of example 8.3.

(12.C) Let $q$ be a power of a prime number $p$ and let $F_q$ be a field with $q$ elements. Let $\overline{\mathbb{F}}_q$ be an algebraic closure of $F_q$ and let $\varphi: \overline{\mathbb{F}}_p \to \overline{\mathbb{F}}_p$ be the automorphism given by $x \mapsto x^q$. Let $h \in F_q[T]$ be a polynomial of degree $n > 0$ which has $n$ distinct zeroes in $\overline{\mathbb{F}}_p$. (This last condition just means that $h \in F_q[T]$ is a product of distinct irreducible factors, i.e., there does not exist an irreducible factor $f$ such that $f^2$ divides $h$.)

(i) If $\alpha$ is a zero of $h$ in $\overline{\mathbb{F}}_p$, show that $\varphi(\alpha)$ is a zero of $h$, too.

(ii) Let $\{\alpha_1, \ldots, \alpha_n\}$ be the set of zeroes of $h$ in $\overline{\mathbb{F}}_p$. Let $\sigma \in S_n$ be the permutation given by the relation $\varphi(\alpha_i) = \alpha_{\sigma(i)}$. Note that the conjugacy class of $\sigma$ in $S_n$ is independent of the chosen ordering of the zeroes $\alpha_i$. Now prove that the discriminant $\Delta(h) \in F_q^*$ is a square in $F_q$ if and only the permutation $\sigma$ is even.

(12.D) With the same notation as in (12.C), show that for $p = 2$, every element $x \in F_q^*$ is a square. If $p$ is odd, show that $x \in F_q^*$ is a square in $F_q$ if and only if $x^{(q-1)/2} = 1$.

(12.E) Determine the class group of the field generated by a zero of the polynomial $T^4 + 3T^2 + 7T + 4$. (Cf. [37], Chap. 9.)
Chapter 13. The class number formula.

In this chapter we compute the residue in \( s = 1 \) of the Dedekind \( \zeta \)-function \( \zeta_F(s) \) associated to a number field \( F \). The result involves the class number of the number field and several other arithmetical invariants that we have studied. It is often called the class number formula.

The Riemann \( \zeta \)-function

\[
\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} \quad (s \in \mathbb{C}, \ \text{Re}(s) > 1)
\]

is not defined for \( s = 1 \). In order to study its behavior as \( s \downarrow 1 \) we consider the partial sums \( \sum_{n=1}^{N} n^{-s} \) for \( s \in \mathbb{R}_{>1} \) and \( N \in \mathbb{Z}_{>0} \). We have

\[
\int_1^N \frac{dx}{x^s} \leq \sum_{n=1}^{N} \frac{1}{n^s} \leq \int_1^N \frac{dx}{x^s}
\]

and therefore

\[
\frac{1}{s-1} (1 - N^{1-s}) \leq \sum_{n=1}^{N} \frac{1}{n^s} \leq \frac{1}{s-1} (1 - N^{1-s})
\]

Multiplying by \( s - 1 \) and letting first \( N \) tend to infinity and then \( s \) tend to 1, we obtain

\[
\lim_{s \to 1} (s-1) \sum_{n=1}^{\infty} \frac{1}{n^s} = 1.
\]

In fact, the Riemann \( \zeta \)-function admits a meromorphic continuation to all of \( \mathbb{C} \) with a single pole of order 1 at 1, but we will neither prove nor use this.

In this section we generalize this result to the Dedekind \( \zeta \)-function \( \zeta_F(s) \) associated to a number field \( F \):

\[
\zeta_F(s) = \sum_{0 \neq I} \frac{1}{N(I)^s} = \prod_p \left( 1 - \frac{1}{N(p)^s} \right)^{-1}
\]

for \( s \in \mathbb{C} \) with \( \text{Re}(s) > 1 \). Here the sum runs over the non-zero ideals of \( \mathcal{O}_F \). The techniques will be analytical in nature. See Heilbronn’s article in [9] or Davenport’s book *Multiplicative Number Theory* for similar techniques. Like the Riemann \( \zeta \)-function, the Dedekind \( \zeta \)-functions admit meromorphic continuations to \( \mathbb{C} \) with only a simple pole at 1. The limit \( \lim_{s \to 1} (s-1)\zeta_F(s) \) which is given in Theorem 13.1, is equal to the residue of \( \zeta_F(s) \) at \( s = 1 \). See Hecke’s Theorem 13.5 for a more complete statement.

**Theorem 13.1. (The Class Number Formula)** Let \( F \) be a number field and let \( \zeta_F(s) \) denote its Dedekind \( \zeta \)-function. Then

\[
\lim_{s \to 1} (s-1)\zeta_F(s) = \frac{2^n (2\pi)^{r_2} h_F R_F}{w_F \sqrt{\Delta_F}}.
\]

Here \( r_1 \) is the number of homomorphism \( F \to \mathbb{C} \) which have their image in \( \mathbb{R} \) and \( 2r_2 \) the remaining number of homomorphism \( F \to \mathbb{C} \). By \( h_F \) we denote the class number of \( F \), by \( R_F \) its regulator, by \( \Delta_F \) the discriminant and, finally, by \( w_F \) the number of roots of unity in \( F \).
Proof. Let $s \in \mathbb{C}$ with $\text{Re}(s) > 1$. By Prop. 6.7, the sum

$$\zeta_F(s) = \sum_{J \neq 0} \frac{1}{N(J)^s}$$

is absolutely convergent. We rewrite it as

$$\zeta_F(s) = \sum_{C \in \mathbb{C}(\mathfrak{O}_F)} \zeta_C(s)$$

where

$$\zeta_C(s) = \sum_{J \in C} \frac{1}{N(J)^s}.$$

Let $C$ be an ideal class and let $I \in C^{-1}$. The map $J \mapsto IJ$ gives a bijection between the class $C$ and the set of principal ideals $\langle\alpha\rangle$ contained in $I$. Therefore we can write

$$\zeta_C(s) = \sum_{\langle\alpha\rangle \subseteq I} \frac{1}{N(\langle\alphaI^{-1}\rangle)^s} = N(I) \sum_{\langle\alpha\rangle \subseteq I} \frac{1}{|N(\alpha)|^s}.$$

In order to calculate this sum, we view the ideal $I$ via the map $\Phi: F \rightarrow F \otimes \mathbb{R}$ as a lattice in the $\mathbb{R}$-algebra $F \otimes \mathbb{R} = \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$.

The units of the algebra $F \otimes \mathbb{R}$ are precisely the vectors that have all their coordinates non-zero. We extend the map $\Psi: \mathbb{C} \rightarrow \mathbb{R}^{r_1 + r_2}$ to $(F \otimes \mathbb{R})^*$:

$$\Psi: (\mathbb{R}^{r_1} \times \mathbb{C}^{r_2})^* \rightarrow \mathbb{R}^{r_1 + r_2}$$

by

$$\Psi(x_1, \ldots, x_{r_1}, z_1, \ldots, z_{r_2}) = \left(\log|x_1|, \ldots, \log|x_{r_1}|, \log|z_1|, \ldots, \log|z_{r_2}|\right),$$

and we extend the norm $N: F \rightarrow \mathbb{R}$ to $F \otimes \mathbb{R}$ by

$$N(x_1, \ldots, x_{r_1}, z_1, \ldots, z_{r_2}) = |x_1| \cdots |x_{r_1}| \cdot |z_1|^2 \cdots |z_{r_2}|^2.$$  

The norm is a homogenous polynomial of degree $n$. Clearly it does not vanish on $(F \otimes \mathbb{R})^*$.

We choose a basis $E$ for the real vector space $\mathbb{R}^{r_1 + r_2}$. Choose a system of fundamental units $\varepsilon_1, \ldots, \varepsilon_{r_1 + r_2 - 1}$ and apply the map $\Psi$. This gives us $r_1 + r_2 - 1$ independent vectors $\Psi(\varepsilon_i)$ that span the subspace of vectors that have the sum of their coordinates equal to zero. The basis $E$ will consist of the vectors $\Psi(\varepsilon_i)$ plus the vector $v = (1, 1, \ldots, 1, 2, 2, \ldots, 2)$ that has 1’s on the real coordinates and 2’s on the complex coordinates.

The proof will be a fairly straightforward consequence of three lemmas that will be stated and proved after the proof of Theorem 13.1.

Consider the subset $\Gamma \subseteq \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$ consisting of the vectors $\mathbf{x} \in \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$ such that the coordinates $\xi_i$ of $\Psi(\mathbf{x})$ with respect to the basis $E$ satisfy $0 \leq \xi_i < 1$ for $1 \leq i \leq r_1 + r_2 - 1$ and such that the first coordinate $x_1$ of $\mathbf{x}$ satisfies $0 \leq \arg(x_1) < \frac{2\pi}{\omega_F}$.

If $r_1 > 0$, i.e., if the first coordinate $x_1$ is real, the condition $0 \leq \arg(x_1) < \frac{2\pi}{\omega_F}$ should be interpreted as $x_1 > 0$. By Lemma 13.2, we have that

$$\zeta_C = N(I)^s \sum_{\alpha \in I \cap \Gamma} \frac{1}{|N(\alpha)|^s} \quad \text{for } s \in \mathbb{C}, \text{ Re}(s) \geq 1.$$
The set $\Gamma$ is a *cone*, i.e. for all $x \in \Gamma$ and $\lambda > 0$ also $\lambda x \in \Gamma$. This can be seen as follows: From

$$\Psi(\lambda x) = \Psi(\lambda) + \Psi(x) = \lambda v + \Psi(x)$$

it follows that, with respect to the basis $E$, the coordinates of $\Psi(\lambda x)$ and $\Psi(x)$ are equal, except possibly the last. Since $\lambda > 0$, the argument of the first coordinate of $x$ is also unchanged. This shows that $\Gamma$ is a cone.

The subset $\Gamma_1 = \{ \gamma \in \Gamma \mid |N(\gamma)| \leq 1 \}$ is bounded and has finite volume. Therefore, by Lemmas 13.3 and 13.4, we have that

$$\lim_{s \to 1} (s - 1)\zeta_C(s) = \lim_{s \to 1} (s - 1)N(I)^s \sum_{\alpha \in I \cap \Gamma} \frac{1}{|N(\alpha)|^s} = N(I) \frac{\operatorname{vol}(\Gamma_1)}{\operatorname{covol}(I)} = N(I) \frac{2^{r_1} \pi^{r_2} R_F}{w_F} \frac{2^{r_2}}{N(I) \sqrt{\Delta_F}}.$$ 

We see that the result does not depend on the ideal class $C$. Therefore, since there are $h_F$ different ideal classes, we find that

$$\lim_{s \to 1} (s - 1)\zeta_F(s) = \sum_C \lim_{s \to 1} (s - 1)\zeta_C(s) = h_F \frac{2^{r_1} \pi^{r_2} R_F}{w_F} \Delta_F$$

as required. \qed

It remains to prove the three Lemma’s.

**Lemma 13.2.** Let $F$ be a number field and let $\Gamma \subset F \otimes \mathbb{R}$ be the cone defined above. Then for a fractional ideal $I$ of $F$ we have that

$$\sum_{(\alpha) \in I} \frac{1}{|N(\alpha)|^s} = \sum_{\alpha \in I \cap \Gamma} \frac{1}{|N(\alpha)|^s}.$$ 

(Nota the first sum runs over the principal ideals $(\alpha)$, while the second runs over elements $\alpha$.)

**Proof.** We show first that $(F \otimes \mathbb{R})^* = O_F^* \cdot \Gamma$: let $(x \in F \otimes \mathbb{R})^*$. Write $\Psi(x)$ with respect to the basis $E$ introduced above.

$$\Psi(x) = \xi_1 \Psi(\varepsilon_1) + \ldots + \xi_{r_1 + r_2 - 1} \Psi(\varepsilon_{r_1 + r_2 - 1}) + \xi_{r_1 + r_2} v.$$ 

Define the unit $\varepsilon$ by

$$\varepsilon = \varepsilon_1^{m_1} \ldots \varepsilon_{r_1 + r_2}^{m_{r_1 + r_2}},$$

where $m_i$ denotes the integral part of $\xi_i$. As a consequence, the first $r_1 + r_2 - 1$ coordinates of $\Psi(\varepsilon^{-1}x)$ are between 0 and 1.

Next consider the first coordinate $y_1$ of $\varepsilon^{-1}x$. Pick a root of unity $\zeta \in F^*$, such that the argument $\varphi$ of $\zeta y_1$ satisfies $0 \leq \varphi < 2\pi/w_F$. We conclude that $\zeta \varepsilon^{-1}x \in \Gamma$ and hence that $x \in O_F^* \cdot \Gamma$ as required. Moreover, this representation of $x \in (F \otimes \mathbb{R})^*$ is unique: suppose that $\varepsilon_1 = \varepsilon_1' \gamma'$ for $\varepsilon_1' \in O_F^*$ and $\gamma, \gamma' \in \Gamma$. Then $u = \varepsilon/\varepsilon_1' = \gamma'/\gamma \in O_F^* \cap \Gamma$. This implies at once that the first $r_1 + r_2 - 1$ coefficients of $\Psi(u)$ are zero. Since $u$ is a unit, the sum of the coefficients is zero and therefore the last coefficient is also zero. This implies that $u \in \ker(\Psi) = \mu_F$. Since the arguments of the first coordinate in $F \otimes \mathbb{R}$ of both $\gamma$ and $\gamma'$ are between 0 and $2\pi/w_F$, we conclude that $u = 1$ and the unicity follows.

The lemma now follows from the fact that every principal ideal $(\alpha) \subset F \otimes \mathbb{R}$ has precisely one generator in $\Gamma$. Indeed, $\alpha \in (F \otimes \mathbb{R})^*$, so by the above there is a unique unit $\varepsilon$ such that $\varepsilon\alpha \in \Gamma$. \qed
Lemma 13.3. Let \( L \) be a lattice in \( \mathbb{R}^n \) and let \( \Gamma \subset \mathbb{R}^n \) be a cone. Let \( N \) be a homogeneous polynomial of degree, that does not vanish on \( \Gamma \). Assume that \( \Gamma_1 = \{ \gamma \in \Gamma \mid |N(\gamma)| \leq 1 \} \) is bounded and has finite volume. Then

\[
\lim_{s \to 1} \sum_{x \in L \cap \Gamma} \frac{1}{|N(x)|^s} = \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)}.
\]

Proof. Let

\[
\nu(r) = \#(L \cap \Gamma_1) = \#\{x \in L : |N(x)| \leq r^n\}.
\]

Since \( \Gamma_1 \) is bounded, \( \nu(r) \) is finite. The equality follows from the fact that \( N(x) \) is homogeneous of degree \( n \). By the definition of the Riemann integral we have that

\[
\text{vol}(\Gamma_1) = \lim_{r \to \infty} \nu(r) \text{covol}(\frac{1}{r}L)
\]

and, equivalently

\[
\lim_{r \to \infty} \frac{\nu(r)}{r^n} = \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)}.
\]

Next, we enumerate the vectors \( x_1, x_2, x_3, \ldots \) in \( \Gamma \cap L \):

\[
0 < |N(x_1)| \leq |N(x_2)| \leq |N(x_3)| \leq \ldots
\]

and for \( k \geq 1 \) we put

\[
r_k = |N(x_k)|^{\frac{1}{n}}.
\]

It is immediate that \( k \leq \nu(r_k) \) and that for every \( \varepsilon > 0 \) one has that \( \nu(r_k - \varepsilon) \leq k - 1 < k \). Therefore

\[
\frac{\nu(r_k - \varepsilon)}{(r_k - \varepsilon)^n} \leq \left( \frac{r_k - \varepsilon}{r_k} \right)^n \leq \frac{\nu(r_k)}{r_k^n}
\]

and letting \( \varepsilon \to 0 \) we find that

\[
\lim_{k \to \infty} \frac{k}{r_k^n} = \lim_{k \to \infty} \frac{\nu(r_k)}{r_k^n} = \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)} > 0.
\]

It follows that for \( \varepsilon > 0 \) sufficiently small and \( k_0 \in \mathbb{Z}_{>0} \) sufficiently large, we have for all \( k \geq k_0 \) that

\[
\left( \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)} - \varepsilon \right) \frac{1}{k} < \left( \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)} + \varepsilon \right) \frac{1}{k}
\]

and hence for \( s \in \mathbb{R}_{>1} \) that

\[
\left( \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)} - \varepsilon \right)^s (s - 1) \sum_{k > k_0} \frac{1}{k^s} < \left( \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)} + \varepsilon \right)^s (s - 1) \sum_{k > k_0} \frac{1}{k^s}.
\]

Now we let \( s \) tend to 1. Using that \( \lim_{s \to 1} (s - 1) \sum_{1 \leq k < k_0} 1/k^s = 0 \), and using the fact that the Riemann \( \zeta \)-function \( \zeta(s) = \sum_{k=1}^{\infty} 1/k^s \) has a pole of order 1 at \( s = 1 \) with residue 1, we obtain that for sufficiently small \( \varepsilon > 0 \)

\[
\frac{\text{vol}(\Gamma_1)}{\text{covol}(L)} - \varepsilon < \lim_{s \to 1} \sum_{k=1}^{\infty} \frac{1}{|N(x_k)|^s} < \frac{\text{vol}(\Gamma_1)}{\text{covol}(L)} + \varepsilon.
\]

This proves the lemma. \( \square \)
**Lemma 13.3.** Let $F$ be a number field and let $\Gamma \subset F \otimes \mathbb{R}$ be the cone defined above. Then

(i) $$\text{vol}(\Gamma_1) = \frac{2^{r_1} \pi^{r_2} R_F}{w_F}.$$ 

(ii) Let $I$ be a fractional ideal in $F$, then the image of $I$ in $F \otimes \mathbb{R}$ satisfies $$\text{covol}(I) = 2^{-n} N(I) \sqrt{\Delta_F}.$$ 

**Proof.** The set $\Gamma_1$ consists of those vectors $x = (x_1, \ldots, x_{r_1}, y_1, \ldots, y_{r_2}) \in (F \otimes \mathbb{R})^*$, for which $0 \leq \arg(x_1) < \pi/w_F$, for which $N(x) \leq 1$ and for which $0 \leq \xi_1, \ldots, \xi_{r_1+r_2-1} \leq 1$, where the $\xi_i$ are defined by

$$\Psi(x) = \xi_1 \Psi(\varepsilon_1) + \cdots + \xi_{r_1+r_2-1} \Psi(\varepsilon_{r_1+r_2-1}) + \xi_{r_1+r_2} \nu.$$ 

It is clear that, if we drop the condition that $0 \leq \arg(x_1) < \pi/w_F$, the volume of $\Gamma_1$ is multiplied by $w_F$. If, moreover, we add the conditions that $x_i > 0$ for all real coordinates $i$, i.e., for $1 \leq i \leq r_1$, the volume is multiplied by $2^{-n}$:

$$\text{vol}(\Gamma_1) = \frac{2^{r_1}}{w_F} \cdot \text{vol}\left\{ \begin{array}{l} x \in (F \otimes \mathbb{R})^* \mid \begin{array}{c} 0 \leq \xi_1, \ldots, \xi_{r_1+r_2-1} \leq 1 \text{ and } x_1, \ldots, x_{r_1} > 0 \\
|\log(x_1)| \cdots |\log(x_{r_1}|) \cdots |\log(y_{r_2})| \leq 1 \end{array} \end{array} \right\}.$$ 

We use polar coordinates for the complex coordinates: write $z_k = \rho_k e^{i \varphi_k}$ and it is convenient to work with $x_{r_1+k} = \rho_k^2$ rather than $\rho_k$. We find that

$$\text{vol}(\Gamma_1) = \frac{2^{r_1} \pi^{r_2}}{w_F} \int_W dx_1 \cdots dx_{r_1+r_2-1}$$

where $W$ is the set of vectors $x = (x_1, \ldots, x_{r_1+r_2}) \in (F \otimes \mathbb{R})^*$ for which $x_1, \ldots, x_{r_1+r_2} > 0$ and $\sum_{i=1}^{r_1+r_2} \log(x_i) < 0$ and for which

$$\left( \begin{array}{c} \log(x_1) \\
\vdots \\
\log(x_{r_1+r_2}) \end{array} \right) = \xi_1 \Psi(\varepsilon_1) + \cdots + \xi_{r_1+r_2-1} \Psi(\varepsilon_{r_1+r_2-1}) + \xi_{r_1+r_2} \nu$$

with $0 \leq \xi_1, \ldots, \xi_{r_1+r_2-1} < 1$.

Observe that $\xi_{r_1+r_2} = -\sum_i \log(x_i)$. Clearly, the above integral is most conveniently evaluated by integration with respect to the variables $\xi_i$. So, we make the change of variables according to the formulas given in the description of the set $W$. It is not difficult to calculate the Jacobian $J$ of this transformation. One finds

$$\text{vol}(\Gamma_1) = \frac{2^{r_1} \pi^{r_2}}{w_F} \int_0^1 \cdots \int_0^1 \int_{-\infty}^\infty |\det(J)| \, d\xi_1 \cdots d\xi_{r_1+r_2}$$

where

$$J = \begin{pmatrix} x_1 \log \| \varphi_1(\varepsilon_1) \| & \cdots & x_1 \log \| \varphi_1(\varepsilon_{r_1+r_2-1}) \| & x_1 \\
\vdots & \cdots & \vdots & \vdots \\
x_{r_1+r_2} \log \| \varphi_{r_1+r_2}(\varepsilon_1) \| & \cdots & x_{r_1+r_2} \log \| \varphi_{r_1+r_2}(\varepsilon_{r_1+r_2-1}) \| & 2x_{r_1+r_2} \end{pmatrix}.$$
We conclude that
\[
\operatorname{vol}(\Gamma_1) = \frac{2^{r_1} \pi^{r_2}}{w_F} R_F \int_0^1 \cdots \int_0^1 \int_{-\infty}^0 n x_1 \cdots x_{r_1+r_2-2} d\xi_1 \cdots d\xi_{r_1+r_2} = \frac{2^{r_1} \pi^{r_2} R_F}{w_F}.
\]
as required. \(\square\)

Finally, we formulate, without proof, Hecke’s Theorem [26]. (E. Hecke, German mathematician, 1887–1947). Hecke’s proof is elaborate. It exploits \(\Theta\)-functions and their functional equations. Later in 1959, J.T. Tate gave a simpler proof, based on harmonic analysis on adelic groups \([9,32]\).

The \(\Gamma\)-function \(\Gamma(s)\) below, is for \(s \in \mathbb{C}\) with \(\text{Re}(s) > 0\) is defined by
\[
\Gamma(s) = \int_0^\infty e^{-t s} \frac{dt}{t}.
\]

**Theorem 13.5.** (E. Hecke, 1910) Let \(F\) be a number field and let \(\zeta_F(s)\) denote its Dedekind \(\zeta\)-function.
(i) (Euler product.)
\[
\zeta_F(s) = \sum_{\mathcal{I} \neq \mathcal{I}} \frac{1}{N(I)^s} = \prod_p \left(1 - \frac{1}{N(p)^s}\right)^{-1}
\]
for \(s \in \mathbb{C}\) with \(\text{Re}(s) > 1\). Here the sum runs over the non-zero ideals of the ring of integers \(O_F\) and the product runs over the non-zero prime ideals \(p\) of this ring.

(ii) (Analytic continuation.) The function \(\zeta_F(s)\) admits a meromorphic extension to \(\mathbb{C}\). It has only one pole of order 1 at \(s = 1\). The residue is
\[
\frac{2^{r_1}(2\pi)^{r_2} h_F R_F}{w_F \sqrt{\Delta}}
\]
where the notation is as in Theorem 13.1.

(iii) (Functional equation.) The function
\[
Z(s) = |\Delta_F|^{s/2} \left(\frac{\pi}{2}\right)^{s/2} \Gamma(s) (2\pi)^{-s} \Gamma(\frac{s}{2}) \zeta_F(s)
\]
satisfies \(Z(s) = Z(1-s)\).

(iv) (Zeros.) The \(\zeta\)-function has a zero of multiplicity \(r_1 + r_2\) at each even negative integer \(-2k\). If \(F\) is not totally real (i.e., \(r_2 \neq 0\)) then it has a zero of multiplicity \(r_2\) at each odd negative integer \(-2k+1\). At \(s = 0\) it has a zero of order \(r_1 + r_2 - 1\) with leading coefficient of the Taylor expansion at 0 equal to \(-h_F R_F / w_F\). These are the so-called trivial zeroes. All other zeroes \(\rho\) satisfy \(0 \leq \text{Re}(\rho) \leq 1\).

**Proof.** We have proved (i) in section 6. For a proof of (ii) and (iii) we refer to Lang’s book [32]. Part (iv) is a rather easy consequence of the properties of the \(\Gamma\)-function [2].

For the case \(F = \mathbb{Q}\), i.e., for the Riemann \(\zeta\)-function \(\zeta(s) = \zeta_{\mathbb{Q}}(s)\), the results in Theorem 13.5 were all proved by Euler and Riemann. Riemann observed that many zeroes \(\rho\) of \(\zeta(s)\) satisfy \(\text{Re}(\rho) = 1/2\) and conjectured that this is true for all non-trivial zeroes. This is the celebrated *Riemann Hypothesis* which is still unproven. Its truth is considered very likely and would have
important consequences. A very weak version of it was proved by Hadamard and De la Vallée Poussin in 1899. They showed that \( \Re \rho \neq 1 \) for every zero \( \rho \) of \( \zeta(s) \). As an immediate consequence they deduced the famous \textit{Prime Number Theorem} [24]:

\[
\# \{p < X \mid p \text{ is prime} \} \approx \frac{X}{\log X}.
\]

The Riemann Hypothesis has been numerically tested [51]: The \( 3 \cdot 10^9 \) zeroes \( \rho \) with \( |\Im \rho| < 545439823.15 \ldots \) all have their real parts equal to \( 1/2 \).

The Generalized Riemann Hypothesis is the statement that for every number field \( F \), all non-trivial zeroes of \( \zeta_F(s) \) have their real parts equal to \( 1/2 \). Needless to say, this important conjecture has not been proved either.

There are analogues of the Riemann \( \zeta \)-function in algebraic geometry. For some of these functions the analogue of the Riemann Hypothesis has been proved, e.g. for zeta functions of curves over finite fields by A. Weil [53] in 1948. This result was extended by P. Deligne [13] to smooth and proper varieties over finite fields in 1973.

In the introduction we mentioned the recent proof by A. Wiles of Fermat’s Last Theorem. The most important step in this proof is the proof of an analogue of part (iii) of Theorem 13.5 for the \( \zeta \)-functions associated to \textit{elliptic curves} over \( \mathbb{Q} \). See the article by Rubin and Silverberg [46].

**Exercises**

(13.A) Show that the Dedekind \( \zeta \)-function of \( \mathbb{Q}(i) \) satisfies

\[
\zeta_{\mathbb{Q}(i)}(s) = \sum_{n=1}^{\infty} \frac{(-1)^{(n-1)/2}}{n^s}.
\]

Verify, in a straightforward way, Theorem 13.1 for the Dedekind \( \zeta \)-function of \( \mathbb{Q}(i) \).

(13.B) Verify that the set \( \Gamma_1 \) occurring in the proof of Theorem 13.1, is bounded.

(13.C) The \( \Gamma \)-function \( \Gamma(s) \) is for \( s \in \mathbb{C}, \Re(s) > 0 \) is defined by

\[
\Gamma(s) = \int_0^\infty e^{-t} t^{s-1} \, dt.
\]

Show

(i) for every \( s \in \mathbb{C}, \Re(s) > 0 \) one has that \( \Gamma(s+1) = s\Gamma(s) \);

(ii) the \( \Gamma \)-function admits a meromorphic extension to \( \mathbb{C} \) with poles at \( 0, -1, -2, \ldots \) of order 1.

The residue at \( -k \) is \( (-1)^k/k! \);

(iii) \( \Gamma(s)\Gamma(1-s) = \pi/\sin(\pi s) \) for \( s \in \mathbb{C} - \mathbb{Z} \).

*(13.D) Let \( F_q \) be a finite field with \( q \) elements. Let \( \zeta(s) \) denote the \( \zeta \)-function of the ring \( F_q[T] \):

\[
\zeta_{F_q(T)}(s) = \sum_{I \neq 0} \frac{1}{N(I)^s}.
\]

(Here the product runs over the non-zero ideals \( I \) and \( N(I) = [F_q[T]: I] \).) Show that

\[
\zeta_{F_q(T)}(s) = \frac{1}{1 - q^{-1-s}}.
\]

What is the \( \zeta \)-function of the ring \( F_q[X,Y]/(X^2+Y^2+1) \)? (Hint: show that the conic \( X^2 + Y^2 + 1 = 0 \) is isomorphic to the projective line over \( F_q \).)
