

Homework 7. ISOMAP & LLE

Instructor: Yuan Yao

Due: Tuesday April 26, 2016

The problem below marked by * is optional with bonus credits.

1. *Order the faces:* The following dataset contains 33 faces of the same person ($Y \in \mathbb{R}^{112 \times 92 \times 33}$) in different angles,

<http://math.stanford.edu/~yuany/course/data/face.mat>

You may create a data matrix $X \in \mathbb{R}^{n \times p}$ where $n = 33, p = 112 \times 92 = 10304$ (e.g. `X=reshape(Y, [10304, 33])'`; in matlab).

- (a) Explore the MDS-embedding of the 33 faces on top two eigenvectors: order the faces according to the top 1st eigenvector and visualize your results with figures.
 - (b) Explore the ISOMAP-embedding of the 33 faces on the $k = 5$ nearest neighbor graph and compare it against the MDS results. Note: you may try Tenenbaum's Matlab code <http://math.stanford.edu/~yuany/course/data/isomapII.m>, or see the full package <http://isomap.stanford.edu/IsomapR1.tar>
 - (c) Explore the LLE-embedding of the 33 faces on the $k = 5$ nearest neighbor graph and compare it against ISOMAP. Note: you may try the following Matlab code <https://www.cs.nyu.edu/~roweis/lle/code/lle.m>
2. *Nyström method for large scale eigen-decomposition:* In class, we have shown that every manifold learning algorithm can be regarded as Kernel PCA on graphs: (1) given N data points, define a neighborhood graph with N nodes for data points; (2) construct a positive semidefinite kernel K ; (3) pursue spectral decomposition of K to find the embedding (using top or bottom eigenvectors). However, this approach might suffer from the expensive computational cost in spectral decomposition of K if N is large and K is non-sparse, e.g. ISOMAP and MDS.

To overcome this hurdle, Nyström method leads us to a scalable approach to compute eigenvectors of low rank matrices. Suppose that an N -by- N positive semidefinite matrix $K \succeq 0$ admits the following block partition

$$K = \begin{bmatrix} A & B \\ B^T & C \end{bmatrix}. \quad (1)$$

where A is an n -by- n block. Assume that A has the spectral decomposition $A = U\Lambda U^T$, $\Lambda = \text{diag}(\lambda_i)$ ($\lambda_1 \geq \lambda_2 \geq \dots \lambda_k > \lambda_{k+1} = \dots = 0$) and $U = [u_1, \dots, u_n]$ satisfies $U^T U = I$.

- (a) Assume that $K = XX^T$ for some $X = [X_1; X_2] \in \mathbb{R}^{N \times k}$ with the block $X_1 \in \mathbb{R}^{n \times k}$. Show that X_1 and X_2 can be decided by:

$$X_1 = U_k \Lambda_k^{1/2}, \quad (2)$$

$$X_2 = B^T U_k \Lambda_k^{-1/2}, \quad (3)$$

where $U_k = [u_1, \dots, u_k]$ consists of those k columns of U corresponding to top k eigenvalues λ_i ($i = 1, \dots, k$).

- (b) Show that for general $K \succeq 0$, one can construct an approximation from (2) and (3),

$$\hat{K} = \begin{bmatrix} A & B \\ B^T & \hat{C} \end{bmatrix}. \quad (4)$$

where $A = X_1 X_1^T$, $B = X_1 X_2^T$, and $\hat{C} = X_2 X_2^T = B^T A^\dagger B$, A^\dagger denoting the Moore-Penrose (pseudo-) inverse of A . Therefore $\|\hat{K} - K\|_F = \|C - B^T A^\dagger B\|_F$. Here the matrix $C - B^T A^\dagger B =: K/A$ is called the (generalized) *Schur Complement* of A in K .

- (c) Explore Nyström method on the Swiss-Roll dataset (http://isomap.stanford.edu/swiss_roll_data.mat contains 3D-data X) with ISOMAP. To construct the block A , you may choose either of the following:

n random data points;

n landmarks as minimax k -centers (<http://math.stanford.edu/~yuany/course/data/kcenter.m>);

Some references can be found at:

- (d) *Assume that A is invertible, show that

$$\det(K) = \det(A) \cdot \det(K/A),$$

- (e) *Assume that A is invertible, show that

$$\text{rank}(K) = \text{rank}(A) + \text{rank}(K/A).$$

- (f) *Can you extend the identities in (c) and (d) to the case of noninvertible A ? A good reference can be found at,
